abstract: Many physical models require the simulation of a large number (N) of particles interacting through pair-wise inverse square law forces. N-body simulations are employed in fluid-dynamics, biochemistry, astrophysics, electrodynamics and molecular dynamics. The computational problem is intrinsically hard and these simulations are time-intensive. Existing algorithms exploit either the spatial proximity of particles or the temporal proximity of states. In this thesis, we formally combine the two approaches and present an algorithm with sequential time complexity $O(N^{4/3})$ to integrate N uniformly distributed particles in 3D over one crossing time against the $O(N^{8/3})$ complexity of the direct method. Under reasonable assumptions, our algorithm is optimal. The core of the algorithm is the temporal multipole expansion of the field in terms of the space-time coordinates of the field-point. We also present efficient parallel algorithms on the 2D and 3D Mesh and Hypercube which amortize communication costs through temporal multipole expansions. The parallel algorithms offer an order of magnitude improvement over existing algorithms for even 10^{4} particles. A sequential implementation of the algorithm for two-dimensional N-body systems shows the predicted asymptotic scaling. A parallel version on a 16-processor Intel iPSC/860 machine is also in conformance with theoretical expectations.

title: Ready, Set, Go: Structural Operational Semantics for Linear-Time Process Algebras
abstract: We investigate the relationship between operational semantics, equational semantics, and ready equivalence (a well-known relative of failure equivalence and testing equivalence) in process algebra. We give a class of structural operational semantic rules, called winterized rules, which define operations respecting ready equivalence. The class of winterized rules is surprisingly broad; it includes some copying operations which would seem to violate ready equivalence. Membership in this class is decidable in $O(n^{2})$ time. We show that for any process algebra defined by such rules has complete equational axiom system. These methods - winterizability in particular - apply mutatis mutandis to other linear-time process equivalences.

title: Structural Operational Semantics for Weak Bisimulations
abstract: In this study, we present rule formats for four main notions of bisimulation with silent moves. Weak bisimulation is a congruence for any process algebra defined by WB cool rules; we have similar results for rooted weak bisimulation (Milner's "observational equivalence"), branching bisimulation, and rooted branching bisimulation. The theorems stating that, say, observational equivalence is an appropriate notion of equality for CCS are corollaries of the results of this paper. We also give sufficient conditions under which equational axiom systems can be generated from operational rules. Indeed, many equational axiom systems appearing in the literature are instances of this general theory.

title: Chain Models of Physical Behavior for Engineering Analysis and Design
abstract: The relationship between geometry (form) and physical behavior (function) dominates many engineering activities. The lack of uniform and rigorous computational models for this relationship has resulted in a plethora of inconsistent (and thus usually incompatible) computer aided design (CAD) tools and systems, causing unreasonable overhead in time, effort, and cost, and limiting the extent to which CAD tools are used in practice. It seems clear that formalization of the relationship between form and function is a prerequisite to taking full advantage of computers in automating design and analysis of engineering systems. We present a unified computational model of physical behavior that explicitly links geometric and physical representations. The proposed approach characterizes physical systems in terms of their algebraic-

topological properties: cell complexes, chains, and operations on them.

title: Distributed ML: Abstractions for Efficient and Fault-Tolerant Programming
abstract: Despite the availability, inherent parallelism, and potential fault tolerance of networked workstations and microcomputers, most programmers do not write distributed code. Those that do are often overwhelmed by the asynchrony, concurrency, and tricky failure behaviour inherent in such systems. In this thesis, we describe the design and implementation of a new programming language called Distributed ML. Distributed ML provides a programming construct called a port group that hides the sources of complexity listed above and can be implemented efficiently. Port groups are intermachine multicast channels which provide membership and failure information to application programmers. Although inherently asynchronous, port groups guarantee the delivery of data sent through them and can order such data in several different ways, thereby providing many of the assurances of synchronous communication. Port groups are general-purpose communication abstractions that can be used to transfer information between machines, between processes on the same machine, and between threads within the same process. In this thesis, we demonstrate that efficient distributed programs-even highly available and fault-tolerant distributed programs-can be quickly developed, easily reasoned about, and properly coded in a well-designed high level programming language. First, we provide an implementation and description of port groups in the context of the Concurrent ML concurrent programming language, which is a superset of the Standard ML general-purpose programming language. Second, we introduce a formal theory for relating the membership and ordering properties of port groups. Finally, we argue that our implementation matches the formal specification.

title: Unreliable Failure Detectors for Asynchronous Distributed Systems
abstract: It is well-known that several fundamental problems of fault-tolerant distributed computing, such as Consensus and Atomic Broadcast, cannot be solved in asynchronous systems with crash failures. These impossibility results stem from the lack of reliable failure detection in such systems. To circumvent such impossibility results, we introduce the concept of unreliable failure detectors that can make mistakes, and study the problem of using them to solve Consensus (and Atomic Broadcast). It is easy to solve Consensus using a "perfect" failure detector (one that does not make mistakes). But is perfect failure detection necessary to solve Consensus? We show that Consensus is solvable with unreliable failure detectors, even if they make an infinite number of mistakes. This leads to the following question: What is the "weakest" failure detector for solving Consensus? We introduce a notion of algorithmic reducibility that allows us to compare seemingly incomparable failure detectors. Using this concept, we show that one of the failure detectors that we introduce here is indeed the weakest failure detector for solving Consensus in asynchronous systems with a majority of correct processes. We also show that Consensus and Atomic Broadcast are equivalent in asynchronous systems. Thus all our results regarding the solvability of Consensus using failure detectors, apply to Atomic Broadcast as well. The work in this thesis was funded by an IBM graduate fellowship and grants from NSF, DARPA/NASA, the IBM Endicott Programming Laboratory, Siemens Corp. and the Natural Sciences and Engineering Research Council of Canada.

title: Techniques for Probabilistic Analysis and Randomness-Efficient Computation
abstract: Randomness is well-recognized as an important computational resource in theoretical computer science. Not only are there classical problems for which the only known "efficient" solutions are randomized, but there are problems for which randomness can be used to circumvent deterministic lower bounds. However, standard tools available for probabilistic analysis such as the Chernoff-Hoeffding bounds are not sufficiently powerful in all situations; second, since there are no known "true" sources of randomness, there is a need to develop general techniques for reducing/removing randomness from randomized algorithms. This thesis addresses these two issues. Certain types of scheduling and resource allocation problems in a distributed setting can be modeled as edge coloring problems. In Chapter 2, we present a fast and simple randomized algorithm for edge coloring a graph, in the synchronous distributed point-to-point model of computation. Our algorithm computes an edge-coloring of a graph G with n nodes and maximum degree Δ with at most $(1.6 + \epsilon) \Delta + O(\log^{2+\delta} n)$ colors with high probability, for any fixed $\epsilon, \delta, greater than 0$. To analyze our algorithm, we introduce techniques for proving upper bounds on the tails of random variables, extending the Chernoff-Hoeffding (CH) bounds to some types of dependent random variables. This is joint work with A. Panconesi [91]. In Chapter 3, we show that the CH bounds for the tails of the sums of bounded and independent random variables $X_{1}, \ldots, X_{n}$ require only limited independence among the X_{i}s. We show that if $X_{1}, \ldots, X_{n}$ lie in [0,1] and are k-wise independent, then $Pr(X \geq E[\sum_{i}X_{i}](1 + \delta))$ can be upper bounded by the CH bound, if $k \geq \mu \cdot min\{\delta,\delta^{2}\}$. This leads to algorithms that require a reduced amount of randomness for any analysis which uses the CH bounds. This is joint work with J.P. Schmidt and A. Siegel [108]. In Chapter 4, we present an RNC^{2} algorithm for the perfect matching problem which uses $O(\log Z)$ random bits where Z is any given upper bound on the number of perfect matchings in the graph, generalizing results of Grigoriev and Karpinski. Underlying our algorithm is a randomness-optimal generalization of the Isolating Lemma of Mulmuley, Vazirani and Vazirani, which also leads to other applications. This is joint work with S. Chari and P. Rohatgi [26].

title: Register Renaming and Dynamic Speculation: an Alternative Approach
abstract: In this paper, we present a novel mechanism that implements register renaming, dynamic speculation and precise interrupts. Renaming of registers is performed during the instruction fetch stage instead of the decode stage, and the mechanism is designed to operate in parallel with the tag match logic used by most cache designs. It is estimated that the critical path of the mechanism requires approximately the same number of logic levels as the tag match logic, and therefore should not impact cycle time.

title: Systems of Set Constraints with Negative Constraints are NEXPTIME-Complete
abstract: A system of set constraints is a system of expressions $E\subseteq F$ where E and F describe sets of ground terms over a ranked alphabet. Aiken et al. [AKVW93] classified the complexity of such systems. In [AKW93] it was shown that if negative constraints $E\not\subseteq F$ were allowed, then the

problem is decidable. This was done by reduction to a Diophantine problem, the Nonlinear Reachability Problem, which was shown to be decidable. We show that nonlinear reachability is NP-complete. By bounding the reduction of [AKW93] we conclude that systems of set constraints, allowing negative constraints, is NEXPTIME-complete.

title: Towards a Theory of Information Invariants for Cooperating Autonomous Mobile Robots
abstract: In [Don4], we described a manipulation task for cooperating mobile robots that can push large, heavy objects. There, we asked whether explicit local and global communication between the agents can be removed from a family of pushing protocols. In this paper, we answer in the affirmative. We do so by using the general methods of [Don4] analyzing information invariants. We discuss several measures for the information complexity of the task: (a) How much internal state should the robot retain? (b) How many cooperating agents are required, and how much communication between them is necessary? (c) How can the robot change (side-effect) the environment in order to record state or sensory information to perform a task? (d) How much information is provided by sensors? and (e) How much computation is required by the robot? To answer these questions, we develop a notion of information invariants. We develop a technique whereby one sensor can be constructed from others by adding, deleting, and reallocating (a) - (e) among collaborating autonomous agents. We add a resource to (a) - (e) and ask: (f) How much information is provided by the task mechanics? By answering this question, we hope to develop information invariants that explicitly trade-off resource (f) with resources (a) - (e). The protocols we describe here have been implemented in several different forms, and we will show a video reporting on experiments to measure and analyze information invariants

using a pair of cooperating mobile robots for manipulation experiments in our laboratory.

title: Centering, Trust Region, Reflective Techniques for Nonlinear Minimization Subject to Bounds
abstract: Bound-constrained nonlinear minimization problems occur frequently in practice. Most existing methods belong to an active set type which can be slow for large scale problems. Recently, we proposed a new approach [7,6,8] which generates iterates within the strictly feasible region. The method in [8] is a trust region type and, unlike the existing trust region method for bound-constrained problems, the conditions for its strong convergence properties are consistent with algorithm implementation. A reflective technique can be included in the method. In this paper, we motivate techniques which are important for our new approach. Numerical experience on some medium size problems is included.

title: On Properties of Random Reductions
abstract: Randomness is widely accepted as a powerful computational resource because the most elegant and efficient solutions to several computational problems are randomized. A recurrent theme in the theory of randomized computation is the notion of a random reduction. Random reductions are similar to many-one ($\leq^{P}_{m}$) reductions except for the fact that they are carried out by probablistic transducers which may make errors with small probability. Such reductions are used explicitly in many basic results in complexity theory and implicitly in several randomized algorithms. This thesis investigates the properties of random reductions as a tool towards understanding the power and limitations of randomness. We first prove some startling results which indicate that random reductions can be quite successful in reducing harder problems to simpler ones. We then propose the thesis that in many situations there is a sharp {\em probability threshold} which governs just how successful random reductions can be in this regard. As evidence, we prove that for several complexity classes ${\cal C}$, under standard assumptions, there exist corresponding {\em probability thresholds\/} ${\cal C}_T$, such that random reductions with success probability below ${\cal C}_T$ can reduce the hardest languages in ${\cal C}$ to simpler ones but reductions with success probability above ${\cal C}_T$ cannot do so. Based on these thresholds, we then propose a meaningful definition of completeness under random reductions which resolves several anomalies caused by the traditional definitions which did not place much emphasis on the success probability. The results described above depend on standard but unproven complexity-theoretic assumptions. In order to show that such behavior is inherent to random reductions and not an artifact introduced by these assumptions, we also prove that it is present in very high

complexity classes {\em without any assumptions}. In this thesis we also examine other basic aspects of random reducibility. We prove several {\em absolute} separation results between the notions of completeness under various polynomial-time random reductions with different success probabilities and between various random reductions and deterministic polynomial-time reductions. In addition, we also prove new results on the consequences of having random reductions from NP-complete sets to sparse sets.

title: Robust Characterizations of Polynomials and Their Applications to Program Testing
abstract: The study of self-testing and self-correcting programs leads to the search for robust characterizations of functions. Here we make this notion precise and show such a characterization for polynomials. From this characterization, we get the following three applications: First, we can construct simple and efficient self-testers for polynomial functions. Secondly, it provides results in the area of coding theory, by giving extremely fast and efficient error-detecting schemes for some well known codes. Thirdly, this error-detection scheme plays a crucial role in recent results on hardness of approximating some NP-optimization problems.

title: The Local Nature of Δ-Coloring and Its Algorithmic Applications
abstract: Given a connected graph G = (V,E) with $\mid$V$\mid$ = n and maximum degree Δ such that G is neither a complete graph nor an odd cycle, Brooks' theorem states that G can be colored with Δ colors. We generalize this as follows: let G - v be Δ-colored; then, v can be colored by considering the vertices in an O(log$_{\Delta} n$) radius around v and by recoloring an O(log$_{\Delta} n$) length "augmenting path" inside it. Using this, we show that Δ-coloring G is reducible in O(log^{3} n/log Δ) time to (Δ + 1)-vertex coloring G in a distributed model of computation. This leads to fast distributed algorithms and a linear-processor NC algorithm for Δ-coloring.

title: On The Convergence of Reflective Newton Methods for Large-Scale Nonlinear Minimization Subject to Bounds
abstract: We consider a new algorithm, a reflective Newton method, for the problem of minimizing a smooth

nonlinear function of many variables, subject to upper and/or lower bounds on some of the variables. This approach generates strictly feasible iterates by following piecewise linear paths ("reflection" paths) to generate improved iterates. The reflective Newton approach does not require identification of an "activity set". In this report we establish that the reflective Newton approach is globally and quadratically convergent. Moreover, we develop a specific example of this general reflective path approach suitable for large-scale and sparse problems.

title: A Multi-Resolution Technique for Comparing Images Using the Hausdorff Distance
abstract: The Hausdorff distance measures the extent to which each point of a "model" set lies near some point of an "image" set and vice versa. In this paper we describe an efficient method of computing this distance, based on a multi-resolution tessallation of the space of possible transformations of the model set. We focus on the case in which the model is allowed to translate and scale with respect to the image. This four-dimensional transformation space (two translation and two scale dimensions) is searched rapidly, while guaranteeing that no match will be missed. We present some examples of identifying an object in a cluttered scene, including cases where the object is partially hidden from view.

title: An Accelerated Interior Point Method Whose Running Time Depends Only on A
abstract: We propose a "layered-step" interior point (LIP) algorithm for linear programming. This algorithm follows the central path, either with short steps or with a new type of step called a "layered least squares" (LLS) step. The algorithm returns the exact global minimum after a finite number of steps-in particular, after $O(n^{3.5}c(A))$ iterations, where $c(A)$ is a function of the coefficient matrix. The LLS steps can be thought of as accelerating a path-following interior point method whenever near-degeneracies occur. One consequence of the new method is a new characterization of the central path: we show that it composed of at most n^2 alternating straight and curved segments. If the LIP algorithm is applied to integer data, we get as another corollary a new proof of a well-known theorem by Tardos that linear programming can be solved in strongly polynomial time provided that A contains small-integer entries.

title: Computing the Newtonian Graph (Extended abstract)
abstract: A polynomial $f\in \complex[z]$ defines a vector field $N_f(z) = -f(z)/f'(z)$ on $\complex$. Certain degenerate curves of flow in N_f give the edges of the Newtonian graph, as defined by \cite{Sma85}. These give a relation between the roots of f and f', much similar to the linear order, when f has real roots only. We give a purely algebraic algorithm to compute the Newtonian graph and the basins of attraction in the Newtonian field. The resulting structure can be used to query whether two points in $\complex$ are within the same basin of attraction. This gives us an algebraic approach to root-finding using Newton's method. This method extends to rational functions and more generally to any functions on $\complex$ whose flow is algebraic over $\complex(e)$.

title: Implementing File Systems and Object Databases in a Microstorage Architecture
abstract: A microstorage architecture consists of a microstorage kernel and several storage servers. Each storage server implements a storage model that defines a client's view of all the data in the system, how it is stored, retrieved and manipulated. The storage servers are built on top of the microstorage kernel and rely on it to perform the actual data storage and retrieval. The microstorage kernel implements a mechanism and the storage servers each implement specific policies defined by their storage models. Several different storage servers, each implementing a different storage model, may run concurrently over the microstorage kernel and all data in the system is concurrently visible to all the different storage servers. Different application programs, or different parts of the same application program, can use different storage models to manipulate the same data. Microstorage architectures provide a flexible interface and a smooth transition from traditional file systems to more powerful object oriented storage models. Existing applications continue to work correctly unchanged because they use a storage server that implements a traditional file model while new applications may gradually adopt more powerful storage models.

title: An Algorithm for the Newton Resultant
abstract: Given a system of $n+1$ generic Laurent polynomials, for $i \,=\, 1, \ldots, n+1$, $$\eqlabel(\ InputSystem) f_i(\x) \quad = \quad \sum_{q\in \A_i} c_{iq} \,x^q; \qquad q \,=\, (q_1,\ldots,q_n); \qquad \x^q \,=\, x_1^{q_1}x_2^{q_2}\cdots x_n^{q_n}; \eqno(\InputSystem) $$ with (finite) support sets $\A_i \ subset L$, where L is some affine lattice isomorphic to $\Z^n$; we consider algorithms for the {\it Newton resultant} $R(f_1,f_2, \ldots, f_{n+1})$. This is the unique (up to sign) irreducible polynomial with coefficients in $\Z$ and monomials in the c_{iq} which determines whether or not system~(\InputSystem) has common roots in the {\it algebraic torus} $(\C-\{0\})^n$. The resultant depends only on the {\it Newton polytopes} $N_i \,:=\, conv(\A_i) \subset \R^n$ of the sets $\A_i$. Our terminology emphasizes the dependence on the combinatorics of the Newton polytopes. The algebraic torus is the natural setting for us because we are interested in the properties of systems of polynomials which are invariant under symmetries of the affine lattice L, and translation by $q\in L$ corresponds to multiplication by x^q at the level of polynomials. Since x^q may have negative exponents, we restrict to points none of whose coordinates are zero.

title: Towards Accurate and Efficient Volume Rendering
abstract: This thesis is concerned with improvements to algorithms for volume rendering; a technique that provides scientists with the means for visual exploration of three-dimensional data. Despite its numerous successes, and its increasing use within the scientific community, state-of-the-art volume rendering algorithms have many shortcomings. Difficulties include: ensuring the accuracy of the rendered images, producing images with modest computational resources, and rendering the diverse types of data that are currently being produced. The work in this thesis was motivated by the demands of an ongoing visualization project in four-dimensional cardiac visualization. We present solutions to some key problems in ensuring accuracy and in producing algorithms that can scale to handle large datasets. Although the theoretical work in this thesis applies to arbitrary data topologies, our implementations have assumed that the data is defined by sample points on a regular rectilinear grid. In the area of accuracy, we focus on the error that is introduced during volume projection. This phase of the volume rendering process involves the evaluation of the emission-absorption volume rendering line integral. This thesis presents four techniques for controlled precision volume integration. These schema depart from existing approaches in that they provide error bounds along with the solutions they generate. In each case, the error analysis leads to an algorithm for evaluating the integral to any specified tolerance. Our investigations into efficiency issues have resulted in two advances. First, an adaptive error bracketing scheme is presented that builds on the controlled precision volume integration methods. Using adaptive error bracketing, the solution for a viewing ray is continually refined until a user-specified error tolerance is met. The algorithm allows processing of the data without imposing a strict front-to-back or back-to-front evaluation order. Second, a suite of tools are presented that can be used to efficiently compute perspective projections of volume data. These include a paging strategy that is useful when a dataset is too large to fit into RAM memory and a ray splitting technique for adaptive supersampling. The latter technique ensures that all data features contribute to the final image while avoiding overcomputation in regions close to the eyepoint.

title: Developing Efficient Interpreters Based on Formal Language Specifications
abstract: The paper reports on extensions to the MAX system enabling the generation and refinement of interpreters based on formal language specifications. In these specifications, static semantics is defined by an attribution mechanism that allows to enrich syntax trees by control flow graphs. The dynamic semantics is defined by evolving algebras, a framework that has been successfully used to specify realistic programming languages. We apply the combined framework to a non-trivial example language and show how the resulting language specification can be refined in order to improve the efficiency of the generated interpreters. The framework provides enough modularity and flexibility so that such refinements can be carried out by local changes. We explain the implementation of the extensions to MAX and discuss applications of the system.

title: Interprocedural Data Flow Analysis Based on Temporal Specifications
abstract: This paper investigates the specification of data flow problems by temporal logic formulas and proves fixpoint analyses correct. Temporal formulas are interpreted w.r.t. programming language semantics given in the framework of evolving algebras. This enables very high-level specifications, in particular for history sensitive problems. E.g. the classical bit vector analyses can be refined by using information about conditions in branches without having to change their specifications. The general semantics framework makes the approach directly applicable to realistic programming languages. We use the specifications to prove fixpoint implementations of data flow analyses correct. As an example, we develop a powerful interprocedural deadness analysis that uses constant information depending on the context where the active procedure was called. By proving such a combination of backward and forward analyses correct, we illustrate the use of specifications in correctness proofs.

title: Good Features to Track
abstract: No feature-based vision system can work until good features can be identified and tracked from frame to frame. Although tracking itself is by and large a solved problem, selecting features that can be tracked well and correspond to physical points in the world is still an open problem. We propose a feature selection criterion that is optimal by construction because it is based on how the tracker works, as well as a

feature monitoring method that can detect occlusions, disocclusions, and features that do not correspond to points in the world. These methods are based on a new tracking algorithm that extends previous Newton-Raphson style search methods to work under affine image transformations. We test performance with several simulations and experiments on real images.

title: Pictures and Trails: A New Framework for the Computation of Shape and Motion from Perspective Image Sequences
abstract: This report presents a new framework for the computation of shape and motion from a sequence of images taken under perspective projection. The framework is based on two abstractions, the picture and trail loci, that represent respectively the set of all pictures of the same scene and the set of all trails that a point in the world can leave on the image for a given camera trajectory. These abstractions lead to a remarkably clean relation between perspective and orthography. Furthermore, image motion is described in terms of angles between projection rays, thereby eliminating the need to model camera rotation and leading to more stable results. A numerically sound, global minimization method is developed, based on this framework, for the case of a two-dimensional world, but all concepts also hold in three dimensions. Experiments show that the method is rather immune to noise but critically dependent on camera calibration.

title: AML: Attribute Grammars in ML
abstract: Attribute grammars are a valuable tool for constructing compilers and building user interfaces. This paper reports on a system we are developing, called AML (for Attribution in ML), which is an attribute grammar toolkit for building such applications as language-based programming environments using SML. This system builds on the proven technology of efficient attribute evaluation, while using a higher-level foundation for the implementation of interactive systems. It supports a general and uniform platform for building applications that can manipulate attributed terms and allow access to attribute values. We describe the design of the AML system, its current implementation status, and our plans for the future.

title: Real-Time System = Discrete System + Clock Variables
abstract: How can we take a programming language off the shelf and upgrade it into a real-time programming language? Programs such as device drivers and plant controllers must explicitly refer and react to time. For this purpose, a variety of language constructs-including delays, timeouts, and watchdogs-has been put forward. We advocate an alternative answer, namely, to designate certain program variables as clock variables. The value of a clock variable changes as time advances. Timing constraints can be expressed, then, by conditions on clock values. A single new language construct-the guarded wait statement-suffices to enforce the timely progress of a program. Our presentation proceeds in two steps. First, we extend untimed systems (Section 1) with clock variables (Section 2); then we introduce the guarded wait statement (Section 3). The usage of clock variables and the guarded wait statement is illustrated with real-time applications such as round-robin (timeout-driven) scheduling, priority (interrupt-driven) scheduling, and embedded process control (Section 4). Indeed, clock variables generalize naturally to variables that measure environment parameters other than time (Section 5). In keeping with an expository style, all references are clustered in bibliographic remarks at the end of each section. We conclude by pointing to selected literature on formal methods and support tools for our approach to real-time programming (Section 6).

title: Symbolic Model Checking for Real-Time Systems
abstract: We describe finite-state programs over real-numbered time in a guarded-command language with real-valued clocks or, equivalently, as finite automata with real-valued clocks. Model checking answers the question which states of a real-time program satisfy a branching-time specification (given in an extension of CTL with clock variables). We develop an algorithm that computes this set of states symbolically as a fixpoint of a functional on state predicates, without constructing the state space. For this purpose, we introduce a μ-calculus on computation trees over real-numbered time. Unfortunately, many standard program properties, such as response for all nonzero execution sequences (during which time diverges), cannot be characterized by fixpoints: we show that the expressiveness of the timed μ-calculus is incomparable to the expressiveness of timed CTL. Fortunately, this result does not impair the symbolic verification of "implementable" real-time programs-those whose safety constraints are machine-closed with respect to diverging time and whose fairness constraints are restricted to finite upper bounds on clock values. All timed CTL properties of such programs are shown to be computable as finitely approximable fixpoints in a simple decidable theory.

title: Detecting Moving Objects With a Moving Camera by Comparing Edge Contours
abstract: This paper introduces a method for detecting moving objects in a monocular image sequence that is obtained using a moving camera. The method first estimates the motion of the edge contours in a given image frame, by recovering a transformation that best matches each edge contour with the edges in the subsequent frame. Any contour that is not well accounted for by a single transformation is split into subparts. The transformation of each edge contour together with the relative spatial locations of the contours is used to partition the image into regions with similar motions. Hypotheses about the locations of possible moving objects are then made based on these motion regions. One of the key aspects of the approach is that it is based

on estimating the motion of entire edge contours, as opposed to recovering a velocity field that measures the motion of individual points. We present some examples for image sequences taken of animate objects using a hand-held video camera. Keywords: Motion estimation, motion segmentation, edge matching.

title: Chain Models and Finite Element Analysis
abstract: Algebraic-topological chains defined over finite cell complexes have been proposed as a uniform computational means of representing physical objects, systems and properties. In this article, we introduce CHAINS, an algebraic-topological computer language for representing and computing the properties of a wide variety physical systems. In particular, we develop a CHAINS program that implements a finite element approximation to linear elasticity. In the process we illustrate the relationship between finite element analysis and the chain models methodology, showing that while finite element analysis is a specific numerical approximation scheme, CHAINS is a computer language for specifying and representing a variety of physical systems and approximations, of which finite element computations are one example.

title: Visually-Guided Navigation by Comparing Two-Dimensional Edge Images
abstract: We present a method for navigating a robot from an initial position to a specified landmark in its visual field, using a sequence of monocular images. The location of the landmark with respect to the robot is determined using the change in size and location of the landmark in the image, as a function of the motion of the robot. The landmark location is estimated after the first three images are taken, and this estimate is refined as the robot moves. The method can correct for errors in the robot motion, as well as navigate around obstacles. The obstacle avoidance is done using bump sensors, sonar and dead reckoning, rather than visual servoing. The method does not require prior calibration of the camera. We show some examples of the operation of the system.

title: Audio System for Technical Readings
abstract: The advent of electronic documents makes information available in more than its visual form - electronic information can now be display-independent. We describe a computing system, ASTER, that audio formats electronic documents to produce audio documents. ASTER can speak both literary texts and highly technical documents (presently in LaTeX) that contain complex mathematics. Visual communication is characterized by the eye's ability to actively access parts of a two-dimensional display. The reader is active, while the display is passive. This active-passive role is reversed by the temporal nature of oral communication: information flows actively past a passive listener. This prohibits multiple views - it is impossible to first obtain a high-level view and then "look" at details. These shortcomings become severe when presenting complex mathematics orally. Audio formatting, which renders information structure in a manner attuned to an auditory display, overcomes these problems. ASTER is interactive, and the ability to browse information structure and obtain multiple views enables active listening.

title: Algorithmic Investigations in P-Adic Fields
abstract: This thesis is concerned with algorithmic investigations in p-adically closed fields, of which Hensel's field of p-adic numbers is prototypical. The well known analogies between the field of real numbers and the field of p-adic numbers are supplemented from a computational standpoint. We resolve the complexity of the Decision Problem for Fields in the p-adic case. We work in the new nth power formalism for p-adic fields where the correspondence to the reals is most transparent. First we give an alternating exponential time algorithm for deciding linear sentences in the theory of p-adically closed fields. This also translates into a deterministic algorithm running in exponential space or double exponential time. A deterministic quantifier-elimination procedure for the linear fragment running in double exponential time and space is also presented. Next we employ a quantitative version of a Cell Decomposition Lemma due to Denef to give an alternating exponential time decision procedure for the full theory. As usual this also yields a deterministic decision procedure running in double exponential time or in exponential space, and a quantifier elimination procedure running in double exponential time and space. These complexity bounds are demonstrated to be essentially optimal by proving matching lower bounds on the respective problems. We give a simple algorithm to determine all roots among the p-adic integers of a given polynomial equation. This algorithm is a purely symbolic (as opposed to numerical) p-adic version of the classical Newton and Horner iteration methods and has a natural parallel implementation. We also give algorithms for some problems in valued fields and in p-adic semi-algebraic geometry. Finally we give some additional elementary evidence to support the thesis that certain cosets of nth powers are the proper p-adic analogues to signs in the real case. This is done by showing that these coset representatives display similar behavior with respect to functions and their derivatives, as do the signs in the real case.

title: A Generalization of Brooks' Theorem
abstract: Given a connected graph $G = (V, E)$ with n vertices and maximum degree Δ such that $\Delta \geq$ 3 and G is not a complete graph, Brooks' theorem shows that G is Δ-colorable. We prove a generalization of this theorem: assume inductively that all but one vertex v is colored; then, v can be colored by considering the vertices (and their colors) in just an O (log n) radius around v. Our proof uses a probabilistic technique to link the connectivity and diameter of "almost-regular" graphs, which could have other applications too.

title: A Reflective Newton Method for Minimizing a Quadratic FunctionSubject to Bounds on Some of The Variables.
abstract: We propose a new algorithm, a reflective Newton method, for the minimization of a quadratic function of many variables subject to upper and lower bounds on some of the variables. The method applies to a general (indefinite) quadratic function, for which a local minimizer subject to bounds is required, and

is particularly suitable for the large-scale problem. Our new method exhibits strong convergence properties, global and quadratic convergence, and appears to have significant practical potential. Strictly feasible points are generated. Experimental results on moderately large and sparse problems support the claim of practicality for large-scale problems.

title: Tracking Non-Rigid Objects in Complex Scenes
abstract: We consider the problem of tracking non-rigid objects moving in a complex scene. We describe a model-based tracking method, in which two-dimensional geometric models are used to localize an object in each frame of an image sequence. The basic idea is to decompose the image of a solid object moving in space into two components: a two-dimensional motion and a two-dimensional shape change. The motion component is factored out, and the shape change is represented by explicitly storing a sequence of two-dimensional models, one corresponding to each image frame. The major assumption underlying the method is that the two-dimensional shape of an object will change slowly from one frame to the next. There is no assumption, however, that the two-dimensional image motion in successive frames will be small. Thus, the method can track objects that move arbitrarily far in the image from one frame to the next.

title: Reasoning About Programs by Exploiting the Environment
abstract: A method for making aspects of a computational model explicit in the formulas of a programming logic is given. The method is based on a new notion of environment -- an environment augments the state transitions defined by a program's atomic actions rather than being interleaved with them. Two simple semantic principles are presented for extending a programming logic in order to reason about executions feasible in various environments. The approach is illustrated by (i) discussing a new way to reason in TLA and Hoare-style programming logics about real-time and by (ii) deriving the first TLA and Hoare-style proof rules for reasoning about schedulers.

title: Decomposition of Algebraic Functions
abstract: Functional decomposition--whether a function $f(x)$ can be written as a composition of functions $g(h(x))$ in a nontrivial way--is an important primitive in symbolic computation systems. The problem of univariate polynomial decomposition was shown to have an efficient solution by Kozen and Landau [8]. Dickerson [5] and von zur Gathen [11] gave algorithms for certain multivariate cases. Zippel [13] showed how to decompose rational functions. In this paper, we address the issue of decomposition of algebraic functions. We show that the problem is related to univariate resultants in algebraic function fields, and in fact can be reformulated as a problem of resultant decomposition. We give an algorithm for finding a nontrivial decomposition of a given algebraic function if it exists. The algorithm involves genus calculations and constructing transcendental generators of fields of genus zero.

title: A New Approach to Teaching Mathematics
abstract: We propose a new approach to teaching discrete math: First, teach logic as a powerful and versatile tool for discovering and communicating truths; then use this tool in all other topics of the course. We spend 6 weeks teaching an equational style of propositional and predicate calculus, thereby ensuring that students gain a fluency in logical notation and some skill in its use. We teach basic heuristics for developing proofs, and we relate such proofs to more common informal proofs in mathematics. Then, we use logic extensively and rigorously in teaching topics like set theory, relations and functions, a theory of integers, induction, combinatorics, and solving recurrence relations. Success in teaching logic as a tool means that students lose their fear of mathematics and formalism, gain a positive view of rigorous proofs, learn to appreciate the use of syntactic manipulation, and begin using logic in other areas of study. Our experiences in teaching discrete math at Cornell shows that such success is possible.

title: Improved Data Structures for Fully Dynamic Biconnectivity
abstract: We present fully dynamic algorithms for maintaining the biconnected components in general and plane graphs. A fully dynamic algorithm maintains a graph during a sequence of insertions and and deletions of edges or isolated vertices. Let m be the number of edges and n be the number of vertices in a graph. The time per operation of the best known algorithms are $O(\sqrt{n})$ in general graphs and $O(\log n)$ in plane graphs for fully dynamic connectivity and $O(\min\{m^{2/3}, n\})$ in general graphs and $O(\sqrt{n})$ in plane graphs for fully dynamic biconnectivity. We improve the later running times to $(\min\{\sqrt{m}\log n, n \})$ in general graphs and $O(\log^{2}n)$ in plane graphs. Our algorithm for general graphs can also find the biconnected components of all vertices in time $O(n)$. The update times in general graphs are amortized. This shows that the biconnected components of a graph can be dynamically maintained almost as efficiently as the connected components.

title: Simulating Fail-Stop in Asynchronous Distributed Systems
abstract: The fail-stop failure model appears frequently in the distributed systems literature. However, in an asynchronous distributed system, the fail-stop model cannot be implemented. In particular, it is impossible to reliably detect crash failures in an asynchronous system. In this paper, we show that it is possible to specify and implement a failure model that is indistinguishable from the fail-stop model from the point of view of any process within an asynchronous system. We give necessary conditions for a failure model to be indistinguishable from the fail-stop model, and derive lower bounds on the amount of process replication needed to implement such a failure model. We present a simple one-round protocol for implementing one such failure model, which we call simulated fail-stop.

title: Faster SVD for Matrices with Small m/n
abstract: The singular values of a matrix are conventionally computed using either the bidiagonalization algorithm by Golub and Reinsch (1970) when $m/n less than 5/3$, or the algorithm by Lawson and Hanson (1974) and Chan (1982) when $m/n greater than 5/3.$ However, there is an algorithm that is faster and that does not involve a discontinuous choice, as follows: in all cases, perform a QR factorization as in Lawson-Hanson-Chan, but rather than do this right at the beginning, do it after zeros have already been introduced in the first $j = 2n - m$ rows and columns. The same technique applies when computing singular vectors, with one small modification. If left singular vectors are needed, the new algorithm becomes advantageous only when $m greater than 1.2661n$, and the best j in this case is $3n - m$. The benefits of the new algorithm appear in terms of classical scalar floating-point operation counts; the effects of locality and parallelization are not considered in the analysis.

title: Teaching Math More Effectively, Through the Design of Calculational Proofs
abstract: Lower-level college math courses usually avoid using formalism, in both definitions and proofs. Later, when students have mastered definitions and proofs written largely in English, they may be shown how informal reasoning could be formalized, but the impression is left that such formalization would not be worth the effort. The design of proofs is also not taught. Students see proofs and may be asked to develop a few themselves, but there is little or no discussion of principles or strategies for designing proofs. Few are happy with the results of these courses. Generally, students' reasoning abilities are poor, even after several math courses. Many students still fear math and notation, and the development of proofs remains a mystery to most. In short, students are not being equipped with the tools needed to employ mathematics in solving new problems. We believe that this statee of affairs can be improved. This article describes our approach.

title: Empirical Evidence of the Chaotic Behavior of the Hopfield-Tank TSP Model
abstract: Since its introduction, the Hopfield-Tank model for the Traveling Salesman Problem (TSP) has been surrounded by controversial evidence regarding its viability as a model and its capabilities to produce good results to this hard optimization problem. In this paper we investigate the reasons behind the difficulty of obtaining verifiable results and the viability of the model, by investigating the behavior the Hopfield-Tank neural network for the TSP has in circumstances when it is expected to produce identical tours. Our investigations strongly suggest that, when it is expected from the network to converge in a predetermined tour, the neural network converges to almost all possible tours when an insignificant perturbation to the initial conditions is applied. The overall consequence of our findings regarding the viability of the Hopfield-Tank model and the cause of the controversy surrounding the Hopffield-Tank model for the TSP can be summarized by the following: The cause of the Hopfield-Tank neural network for the TSP controversy and the difficulties in reproducing results is the chaotic behavior of the model. The finding of useful results for the TSP using the Hopfield-Tank network are purely casual and not to be attributed to the viability of the model. In essence the Hopfield-Tank neural network for the TSP is as viable as chaotic systems can be.

title: Systems Research in the Age of On-Line Coffee Houses
abstract: For years, we have spoken of a golden era where high performance "super-computers" will be available in local department stores and we will be able to communicate with anyone and any organization we want via computer networks. In the past, we have whimsically said that in this era, computing systems will be used in dramatically different fashion than they are today. That era is here now, with 60-80Mips computers available in local computer shops, "on-line" coffee houses springing up in trendy neighborhoods and National Public Radio broadcasting on the Internet for almost a year. And yet, the way we used computers has not changed dramatically. Clearly, improved speech understanding and generation systems, vision systems and other sophisticated I/O technologies will change our interaction with computers. What will change the content of our interaction with computers? What type of systems research will enable revolutionary changes in the use of computers? In an attempt to provoke discussion about these topics, a talk was presented several times during the spring semester 1994. A slightly different approach to systems research was presented as well as a few new directions that are being undertaken at Cornell. Hopefully, the ideas and questions raised by this presentation will be of use to others. This technical report is rather rough and disorganized, consisting as it does of slides from those talks and textual commentary. I felt it more valuable to make the material available in a timely manner than to wait until the details had been worked out, and the prose polished. It is an experiment and I am interested in the reaction any readers have to this form of presentation. You can also view a World Wide Web version of this document in: http://simlab.cs/cornell.edu/slides/systems/overview/html I am interested in any comments you might have, both on the content of this report and how it is presented. Please send them to: rz@cs.cornell.edu.

title: Lower Bounds for Dynamic Connectivity Problems in Graphs
abstract: We prove lower bounds on the complexity of maintaining fully dynamic k-edge or k-vertex connectivity in plane graphs and in $(k-1)$-vertex connected graphs. We show an amortized lower bound of $\Omega(\log n/k(\log\log n + \log b))$ per edge insertion or deletion or per query operation in the cell probe model, where b is the word size of the machine and n is the number of vertices in G. We also show an amortized lower bound of $\Omega(\log n/(\log\log n + \log b))$ per operation for fully dynamic planarity testing in embedded graphs. These are the first lower bounds for dynamic connectivity problems.

title: Logical Aspects of Set Constraints
abstract: Set constraints are inclusion relations between sets of ground terms over a ranked alphabet. They have been used extensively in program analysis and type inference. Here we present an equational axiomatization of the algebra of set constraints. Models of these axioms are called termset algebras. They are related to the Boolean algebras with operators of Jonsson and Tarski. We also define a family of combinatorial models called topological term automata, which are essentially the term automata studied by Kozen, Palsberg, and Schwartzbach endowed with a topology such that all relevant operations are continuous. These models are similar to Kripke frames for modal or dynamic logic. We establish a Stone duality between termset algebras and topological term automata, and use time to derive a completeness theorem for a related multidimensional modal logic. Finally, we prove a small model property by filtration, and argue that this result contains the essence of several algorithms appearing in the literature on set constraints.

title: A Group Communication Approach for Mobile ComputingMobileChannel: an ISIS Tool for Mobile Services
abstract: This paper examines group communication as an infrastructure to support mobility of users, and presents a simple scheme to support user mobility by means of switching a control point between replicated servers. We describe the design and implementation of a set of tools, called MobileChannel, for use with the ISIS system. MobileChannel is based on a combination of the two replication schemes: the primary-backup approach and the state machine approach. MobileChannel implements a reliable one-to-many FIFO channel, in which a mobile client sees a single reliable server; servers, acting as a state machine, see multicast messages from clients. Migrations of mobile clients are handled as an intentional primary switch, and hands-offs or server failures are completely masked to mobile clients. To achieve high performance, servers are replicated at a sliding-window level. Our scheme provides a simple abstraction of migration, eliminates complicated hand-off protocols, provides fault-tolerance and is implemented within the existing group communication mechanism.

title: The Weakest Failure Detector for Solving Consensus
abstract: We determine what information about failures is necessary and sufficient to solve Consensus in asynchronous distributed systems subject to crash failures. In [CT91], we proved that $\Diamond\cal W$, a failure detector that provides surprisingly little information about which processes have crashed, is sufficient to solve Consensus in asynchronous systems with a majority of correct processes. In this paper, we prove that to solve Consensus, any failure detector has to provide at least as much information as $\Diamond\cal W$. Thus, $\Diamond\cal W$ is indeed the weakest failure detector for solving Consensus in asynchronous systems with a majority of correct processes.

title: Analyzing Teams of Cooperating Mobile Robots
abstract: In [Don4], we described a manipulation task for cooperating mobile robots that can push large, heavy objects. There, we asked whether explicit local and global communication between the agents can be removed from a family of pushing protocols. In this paper, we answer in the affirmative. We do so by using the general methods of [Don4] analyzing information invariants. We discuss several measures for the information complexity of the task of pushing with cooperating mobile robots, and we present a methodology for creating new manipulation strategies out of existing ones. We develop and analyze synchronous and asynchronous manipulation protocols for a small team of cooperating mobile robots that can push large boxes. The protocols we describe have been implemented in several forms on the Cornell mobile robots in our laboratory.

title: Selective Use of Full-Text Databases
abstract: Large files of natural-language text are now available for automatic processing in machine readable form. Such text files may include documents of textbook size, medium-size newspaper articles and short messages and mail items, and the subject matter may be effectively unrestricted. Typically, the stored material is not meant to be read sequentially from beginning to end. Instead, a selective, diagonal reading strategy may be preferred which skips among the text sections and paragraphs in accordance with individual user needs. Methods are described in this study for analyzing text files covering arbitrary subject matter,

constructing links among text segments of varying size in accordance with computed similarities between texts and defining text traversal paths that are responsive to particular user needs. Such selective text traversal is useful in retrieving information from textbooks and instruction manuals and in consulting dictionaries, encyclopedias and other collections of text items. Topics: Hypertext construction, automatic text linking, selective text utilization, diagonal text traversal.

title: Algorithms for On-Line Navigation
abstract: We consider a number of problems faced by a robot trying to navigate inside a simple polygon. Such problems are "on-line"g in the sense that the robot does not have access to the map of the polygon; it must make decisions as it proceeds, based only on what it has seen so far. Specifically, we examine algorithms for the related problems of exploration and search. We present a 5/4-competitive randomized algorithm for exploring a rectilinear polygon; the only privious work here is the deterministic 2-competitive algorithm claimed in Deng, Kameda and Papadimitrou. For the problem of searching for a distinguished point in a polygon, we give a $\sqrt{3}$-competitive algorithm for traversing a street, which improves on a result of Klein by more than a factor of 3. Finally, the techniques we use in exploration and the construction of search patterns are combined to give an algorithm for searching an arbitrary and unknown rectilinear polygon; here, no constant competitive ratio can be achieved, but our algorithm is within a constant factor of optimal in the worst case.

title: Relational Constraint: A Fast Semantic Analysis Technique
abstract: Relational constraint is a new method for fast semantic analysis of computer programs. It starts with a fixed, finite vocabulary of binary relations; for each data type this vocabulary forms a complete lattice. Relational constraint focuses on strengthening relations in this lattice, developing the strongest correct statement it can about the relation between any two objects in its universe. The relational constraint algorithm runs in $O(n^{2})$ time. In this paper, we discuss the motivation for this research, present the algorithm in detail, and show how it fits in the formal framework of abstract interpretation.

title: Information Invariants for Distributed Manipulation
abstract: In [Don4], we described a manipulation task for cooperating mobile robots that can push large, heavy objects. There, we asked whether explicit local and global communication between the agents can be removed from a family of pushing protocols. In this paper, we answer in the affirmative. We do so by using the general methods of [Don4] analyzing information invariants. We discuss several measures for the information complexity of the task: (a) How much internal state should the robot retain? (b) How many cooperating agents are required, and how much communication between them is necessary? (c) How can the robot change (side-effect) the environment in order to record state or sensory information to perform a task? (d) How much information is provided by sensors? and (e) How much computation is required by the robot?

To answer these questions, we develop a notion of information invariants. We develop a technique whereby one sensor can be constructed from others by adding, deleting, and rellocating (a) - (e) among collaborating autonomous agents. We add a resource to (a) - (e) and ask: (f) How much information is provided by the task mechnics? By answering this question, we hope to develop information invariants that explicitly trade-off resource (f) with resources (a) - (e). The protocols we describe here have been implemented in several different forms, and report on experiments to measure and analyze information invariants using a pair of cooperating mobile robots for manipulation experiments in our laboratory.

title: Performance of the ISIS Distributed Computing Toolkit
abstract: The ISIS Toolkit is a programming environment for building process-group structured distributed software. The system is widely used in settings requiring high reliability, strong distributed consistency guarantees, and highspeed communication. In this paper, we describe experimental studies of ISIS performance. Our work explores the impact of hardware support for multicast performance, with a focus on flow control mechanisms. The use of hardware multicast in ISIS has not been discussed elsewhere. One conclusion of the paper is that although ISIS performance is limited primarily by flow control considerations, this type of hardware support can lead to significant performance improvements for certain communication patterns. A second conclusion was that the ISIS flow-control problem is surprisingly difficult. More work in this area, and on the underlying operating system communications layer (UDP), could have significant impact on the system. Keywords and phrases: Distributed computing, performance, process groups, atomic broadcast, causal and total message ordering, cbcast, abcast, multiple process groups, hardware multicast, IP multicast, virtual synchrony, fault- tolerance.

title: A Polynomial-time Algorithm for the Change-Making Problem
abstract: The change-making problem is the problem of representing a given value with the fewest coins possible from a given set of coin denominations. To solve this problem for arbitrary coin systems is NP-hard [L]. We investigate the problem of determining whether the greedy algorithm always produces the optimal result for a given coin system. Chang and Gill [CG] show that this can be solved in time polynomial in the

size of the largest coin and in the number of coins. Kozen and Zaks [KZ] give a more efficient algorithm, and pose as an open problem whether there is an algorithm to solve this problem which is polynomial in the size of the input. In this paper, we will derive such an algorithm. We first obtain a characterization of the smallest coounterexample (if there is one) for which the greedy algorithm is not optimal. We then derive a set of $O(n^2)$ possible values (where n is the number of coins) which must contain the smallest counterexample. Each can be tested with $O(n)$ arithmetic operations, giving us an $O(n^3)$ algorithm.

title: On Program Transformations
abstract: In understanding complex algorithms, the notions of encapsulation and modularization have played a key role. An algorithm is broken into several parts or modules, and understanding of each part is independent of others. In addition, each part contains details that are not needed by other parts and so can be hidden from them. Programming languages provide support for encapsulation and modularization in many different forms. Early programming languages provided the procedure and function as a means for modularization. Later, files were introduced as a means of modularizing programs. More sophisticated mechanisms were then introduced, like modules, packages, structures, and classes. In all these cases, the interface to a module remained the procedure or function call. Programs that use such modules contain calls to functions and procedures for communicating with a module. Ideally, using the operations that are provided by a module should be done in exactly the same way as using operations that are provided by modules should be easy to intermix. In addition, substituting one module for another that has the same functionality but different implementation should involve a minimal amount of effort. Recently, a new programming language, Polya, has been designed, which attempts to support modularization and at the same time incorporate the operations that are provided by the modules in the programming language itself. This is done by a sophisticated type-definition facility and a mechanism for transforming programs at the source-program level. This thesis studies mechanisms for program transformation at the source program level, in the context of Polya. Program transformation is based on a set of transformation rules that prescribe how a part of a program is to be transformed, and a set of directives that prescribe which program variables are to be transformed. We first give an algorithm for processing program transformations as described by the transform construct. The algorithm constructs a coordinate transformation of an abstract program based on a set of transforms and transform directives for transforming program variables. We then study the problem of transforming expressions that have compound types. Both the type constructor and the component expressions of the original expression may be transformed. No extra rules need be added to the bodies of transforms that transform the type constructor and the component expressions. In the sequel we investigate the problem of transforming procedures and functions that have parameters that need to be transformed. Finally, the problem of transforming program-transformation rules is studied. The program transformation techniques are applied to two well-known algorithms. The algorithms are source programs, which are subsequently transformed to programs of conventional programming languages, and then compiled and run.

title: Robust Functional Equations with Applications to Self-Testing/Correcting
abstract: The idea of self-testing/correcting programs, introduced in [BLR90], is a powerful tool for attacking

the problem of program correctness. However, one of the main criticisms of this approach was that it seemed to have limited scope, applying only to linear and low degree polynomial functions. This paper provides results which show that the concept of self-testing/correcting has much broader applications than we previously understood. We concentrate on functions f satisfying functional equations, in particular, those of the form $\forall x,y~~ F[f(x-y), f(x+y), f(x),f(y)]=0$, where F is an algebraic function. We show that self-testers and self-correctors can be found for many such functions, including $\tan{x},{1 \over {1+\ cot{x}}}, {Ax \over {1-Ax}},\cosh{x}$. We make an initial attempt at characterizing properties of functional equations that make them useful for self-testing and self-correcting.

title: Model Checking Strategies for Linear Hybrid Systems
abstract: Linear hybrid systems are dynamical systems whose variables change both discretely and continuously along piecewise linear trajectories; they are useful for modeling digital real-time programs that are embedded in analog environments. Model checking is an algorithmic technique for anlayzing finite- state systems that has recently been extended to certain infinite-state systems, including linear hybrid systems. The method has been implemented in HyTech (The Cornell Hybrid Technology Tool), a symbolic model checker for linear hybrid systems. We report on a new implementation and several experiments with HyTech. The core of HyTech is a semidecision procedure that, given a linear hybrid automaton describing a system and a temporal formula describing a requirement, computes the so-called target region-the linear set of system states that satisfy the requirement. Unfortunately, the verification procedure may not return the target region using a reasonable amount of time and space, or it may not terminate in principle. Thus we have reimplemented the model checker using more efficient data structures that represent linear state sets geometrically, as unions of convex polyhedra, and we have experimented with several strategies that are designed to improve the performance of the model checker further: we (1) simultaneously compute the target region from different directions, (2) encode data as finite-state control, (3) approximate the target region by dropping constraints, and (4) iteratively refine the approximation until sufficient precision is obtained. Interestingly, symbolic model checking (fixpoint computation by iteration) and the polyhedral approximation strategies (3) can be viewed as the abstract interpretation of linear hybrid systems.

title: A Gradient-Based Evidence Measure for Image Matching
abstract: We present a simple yet powerful method to perform point-to-point matching between two images. The method uses an \it{evidence measure}, whose value for a given displacement reflects both the similarity between two locations and the confidence in a correct match. The measure is based on the gradient fields of the images, and can be computed quickly and in parallel. Accumulating the evidence measure for different displacements allows (1) stable computation of correspondences without smoothing across motion boundaries, and (2) detection of dominant motions, which can serve as attention cues in active vision systems. The method works well both on highly textured images and on images containing regions of uniform intensities, and can be used for a variety of applications, including stereo vision, motion segmentation, and object tracking.

title: Implementing and Exploiting Static Speculation on Multiple Instruction Issue Processors
abstract: Trends in processor architecture and design suggest that static speculation will become a candidate for implementation on future high-performance processors. In this dissertation, we shall examine issues related to the implementation and exploitation of static speculation. There are four primary results: 1) Precise Exceptions: Prior work in static speculation has not examined the interaction between exception handling and speculative instructions in any great detail. We investigate this interaction, exhibiting certain problematic subtleties that arise, and show how they can be overcome. 2) Speculative Tagging: Earlier proposals for implementing speculative instructions tended to have several drawbacks, including restricted applicability. We introduce speculative tagging, a new, more general, mechanism for specifying static speculation, and show it is possible to optimize exception recovery through this mechanism. 3) Whole-DAG Scheduling: Recently, there has been some work on scheduling regions of acyclic code larger than a basic block so as to take advantage of static speculation. We describe another such algorithm, known as whole-DAG scheduling, that contains innovations that make it more flexible, and allow it to use better heuristics. 4) Dynamic Speculation: The work on static speculation and exceptions suggested an alternative approach to implementing dynamic speculation. This approach results in simpler hardware than prior schemes, and is consequently cheaper to implement and potentially has a lesser impact on cycle-time. Additionally, we report results of experimental studies measuring the effectiveness of whole-DAG scheduling. In it, we show, among other things, that our scheduling technique can result in near-optimal schedules, and that the selection heuristics we adopt are superior to those used in earlier algorithms.

title: Lower bounds for the complexity of the Hausdorff distance
abstract: The Hausdorff distance is a similarity measure defined between sets in the plane. Algorithms to find the minimum distance as one set is transformed have been described, but few lower bounds are known. We describe new lower bounds for the complexity of the directed Hausddorff distance. We exhibit lower boundconstructions for both sets of points and sets of points and line segments, under translation, rigid motion, translation and scaling, and affine transformation. The results for point sets can also be extended to the undirected Hausdorff distance. As these lower bounds are for the complexity of the graph of the Hausdorff distance as a function of transformation, they do not necessarily bound functions which search this graph, but do give an indication of how complex the search may be.

title: Efficient Hierarchical Radiosity in Complex Environments
abstract: This thesis presents methods for speeding up the global illumination computations by using bounds on error to eliminate work that is not needed for a solution of a given accuracy. This work makes the hieerarchical radiosity approach feasible for complex environments. First, a new radiosity algorithm for efficiently computing global solutions with respect to a constrained set of views is presented. Radiosities of directly visible surfaces are computed to high acccuracy, while those of surfaces having only an indirect effect are computed to an accuracy commensurate with their contribution. The algorithm uses an adaptive subdivision scheme that is guided by the interplay between two closely related transport processes: one propagating power from the light sources, and the other propagating importance from the visible surfaces. By simultaneously refining approximate solutions to the dual transport equations, computation is significantly reduced in areas that contribute little to the region of interest. This approach is very effective for complex environments in which only a small fraction is visible at any time. Our statistics show dramatic speedups over the fastest previous radiosity algorithms for diffuse environments with details at a wide range of scales. A new approach for accelerating hierarchical radiosity by clustering objects is also presented. Previous approaches constructed effective hierarchies by subdividing surfaces, but could not exploit a hierarchical grouping on existing surfaces. This limitation resulted in an excessive number of initial links in complex environments. Initial linking is potentially the most expensive portion of hierarchical radiosity algorithms, and constrains the complexity of the environments that can be simulated. The clustering algorithm presented here operates by estimating energy transfers between collections of objects which maintaining reliable error bounds on each transfer. Two methods of bounding the transfers are employed with different tradeoffs

between accuracy and time. In contrast with the $O(s^2)$ time and space complexity of the initial linking in previous hierarchical radiosity algorithms, the new methods have complexities of $O(s$ log $s)$ and $O(s)$ for both time and space. Using these methods we have obtained speedups of two orders of magnitude for environments of moderate complexity while maintaining comparable accuracy. Finally, the thesis describes a method for reconstructing the radiance functions across the visible surfaces given a global solution to the energy balance equations. This approach greatly reduces artifacts resulting from the choice of constant basis functions used for the global solution.

title: Uniform Actions in Asynchronous Distributed Systems
abstract: We develop necessary conditions for the development of asynchronous distributed software that will perform {\em uniform} actions (events that if performed by any process, must be performed at all processes). The paper focuses on {\em dynamic uniformity}, which differs from the classical problems in that processes continually leave and join the ongoing computation. Here, we first treat a static version of the problem (lacking joins), and then extend the results so obtained to also include joins. Our results demonstrate that in contrast to Consensus, which cannot be solved in asynchronous systems with even a single faulty process, dynamic uniformity can be solved using a failure detection mechanism that makes bounded numbers of

mistakes. Because dynamic uniformity arises in systems that maintain safety within a "primary partition" of a network, our paper provides a rigorous characterization of the framework upon which several existing distributed programming environments are based.

title: Accurate and Reliable Algorithms for Global Illumination
abstract: The simulation of global illumination is one of the most fundamental problems in computer graphics, with applications in a wide variety of areas, such as architecture and lighting design, computer-aided design, and virtual reality. This problem concerns the transport of light energy between reflective surfaces in an environment. During the past decade, radiosity has become the method of choice for simulating global illumination in diffuse environments. Despite much recent progress in efficiency and applicability of radiosity methods, there are several very important open issues remaining: 1) Radiosity images suffer from many visual artifacts, resulting from lack of reliable automatic discretization algorithms; and 2) Current radiosity algorithms do not provide the user with guaranteed bounds or reliable estimates of the approximation errors. As a result, current radiosity systems require very careful and time-consuming user intervention in the discretization process, and the accuracy of the resulting solutions can only be assessed by visual appearance. This thesis presents new radiosity algorithms for diffuse polyhedral environments that address the open problems mentioned above. First, we have improved and combined together two recently developed radiosity approaches: hierarchical radiosity and discontinuity meshing. An improved hierarchical radiosity algorithm that is based on a discontinuity-driven subdivision strategy to achieve better numerical accuracy and faster convergence is used to compute the global distribution of light energy in an environment. Then, a new algorithm based on discontinuity meshing uses the hierarchical solution to reconstruct a visually accurate approximation to the radiance function. Thus, results of high visual quality can be obtained even from coarse global illumination simulations. The solution is performed entirely in object-space, which enables users to "walk" through high-fidelity shaded virtual environments in real time, using appropriate display hardware. Second, we have developed algorithms that compute a posteriori error bounds and estimates for local and total errors in hierarchical radiosity solutions. A conservative algorithm computes guaranteed upper bounds on the errors. A non-conservative algorithm is capable of computing more realistic error estimates more efficiently. These error estimates are used in a new error-driven refinement strategy for hierarchical radiosity, resulting in faster convergence.

title: RANDOMNESS AS A COMPUTATIONAL RESOURCE: ISSUES IN EFFICIENT COMPUTATION
abstract: Probabilistic methods have become an integral part of theoretical computer science. Typically, the use of randomization leads to solutions which are simple, elegant and more efficient than deterministic algorithms. A new research paradigm in randomized computation is to treat random bits as a resource and design algorithms which use random bits efficiently. The motivations for this approach are that algorithms which use fewer random bits are easier to implement. Also, algorithms using very few random bits can be made deterministic. For several problems all known efficient deterministic algorithms are obtained by this process of derandomization. We design new probabilistic techniques that are used to develop randomness--efficient algorithms for combinatorial optimization problems. The first problem we consider is the abstract problem of isolating one of a possibly exponentially sized set of feasible solutions to the input instance. This

tool has been used previously to design algorithms for problems such as perfect matching in graphs, basic problems on matroids and designing random reductions. We design a new technique to solve this problem that is more efficient in the usage of random bits. Using this we derive randomness efficient solutions for the various applications. The randomness complexity of our method is parametrized in terms of the number of feasible solutions. As corollaries we obtain deterministic solutions for special cases of these problems. This new randomness--efficient technique unifies all previously known results for these applications and in many cases gives more efficient algorithms. We prove a strong lower bound which proves that our technique is optimal in the usage of random bits. Another important tool is the concept of random sources whose distribution approximates that of a truly random source. We present a new construction of such sources that is specifically tailored to be easily combined with the algorithmic design method of conditional probabilities. Using this we derive improved deterministic parallel algorithms for several combinatorial optimization problems. We investigate the problem of constructing small sample spaces which satisfy given constraints. For several sets of constraints we present improved constructions of such sample spaces. These have obvious applications to randomness--efficient computation and obtaining deterministic algorithms.

title: Issues in NP-Optimization and Approximation
abstract: Optimization or finding the best solution for a problem amongst several possible ones is one of the central themes in computing. In particular, NP-optimization (NPO) problems, examples of which include such well-known problems like Integer Programming and Traveling Salesperson Problem, have proved to be of great practical and theoretical importance. Different NPO problems exhibit starkly different properties and understanding the structure of these problems and their classification has been a long- standing goal in theoretical computer science. This thesis investigates the properties of NPO problems in two settings. In the first part of the thesis we investigate how the logical expressibility of NPO problems relates to some of their computational properties like approximability and self-improvement. In the second part we study NPO problems in the context of a relativeloy new model called the counterexample model. This allows us to achieve two objectives: Firstly, it gives us a framework to study and analyze incremental computation of optimal or near-optimal solutions in an abstract setting. This is useful because, in practice, for most of the NPO problems, one has to resort to inexact algorithms which work incrementally towards computing a good solution. Secondly, it gives us a way to precisely formulate and study questions about the structure of these problems which we believe are fundamental from theoretical point of view - for example, how much does the knowledge of one solution of a problem help in computing another solution?

title: On Effective Speed-up and Long Proofs of Trivial Theorems in Formal Theories
abstract: In this note we give a very simple proof which shows that in many interesting formal mathematical theories, axiomatizable as well as decidable ones, for every given formalization we can effectively find infinite subsets of trivially true theorems which require as long proofs in the given formalism as the hardest theorems of the theory. Thus showing that for these theories every formalism is doomed to be blind to the triviality of infinite sets of theorems, which can be found effectively. Furthermore, it follows that for all (sufficiently large) constructable tape and time bounds there exists sets whose recognition can be effectively speeded up on infinite subsets and that such sets appear naturally, thus showing that for many concrete problems, every algorithm can be effectively sped-up on infinite subsets.

title: Thinning Context-Free Languages
abstract: A thinning is a kind of transformation suggested by a practical problem in program optimization. We're given a thinning example δ, which is a string with one or more symbols marked. To thin a language with respect to this δ is to edit each word to reflect the observation that the marked symbols of δ are unnecessary and should be omitted. In this paper we'll explore thinnings of context-free languages. When δ is a fully-terminal string we'll define a language $L_{\delta} (G)$ formed by carrying out a thinning procedure on each word in $L(G)$. For a large class of thinning examples--the class for which the language of strings correctly marked for thinning is regular--we will demonstrate that $L_{\delta}(G)$ is a context-free language and that there is an effective procedure for generating a grammar H for which $L(H)$ = $L_{\delta}(G)$. When δ may include non-terminals the problem is more difficult to formalize: we'll define a language $L_{\delta}(G)$ formed by carrying out a thinning procedure on each parse tree generated by G. This yields an extension of the fully-terminal problem which is unsolved and seems very hard. An easier problem follows from defining a language $L_{\Delta}(G)$ formed by thinning the parse trees of G with respect to a set of thinning-tree examples instead of a single thinning-string example. We will develop an effective procedure for generating a grammar H for which $L(H)$ = $L_{\Delta}$$(G)$. By choosing an appropriate thinning set Δ, we can use this method to get an approximate solution to the general problem.

title: The Algorithmic Analysis of Hybrid Systems
abstract: We present a general framework for the formal specification and algorithmic analysis of hybrid systems. A hybrid system consists of a discrete program with an analog environment. We model hybrid systems as finite automata equipped with variables that evolve continuously with time according to dynamical laws. For verification purposes, we restrict ourselves to linear hybrid systems, where all variables follow

piecewise-linear trajectories. We provide decidability and undecidability results for classes of linear hybrid systems, and we show that standard program-analysis techniques can be adapted to linear hybrid systems. In particular, we consider symbolic model-checking and minimization procedures that are based on the reachability analysis of an infinite state space. The procedures iteratively compute state sets that are definable as unions of convex polyhedra in multidimensional real space. We also present approximation techniques for dealing with systems for which the iterative procedures do not converge.

title: Using White Space for Automated Document Structuring
abstract: We present and analyze efficient algorithms for the automated recognition and interpretation of layout structures in electronic documents. The key idea is to use the patterns in the distribution of white space in a document to recognize and interpret its components. The recognition algorithm divides the document into a hierarchy of logical elements; the interpretation algorithms classify these divisions as base-text, tables, indented lists, polygonal drawings, and graphs. We present experimental data and discuss an information access application. Our methodology allows the automatic markup of documents\footnote{For instance in the SGML format} and the creation of multi-level indices and browsing tools for electronic libraries.

title: Testing Multivariate Linear Functions:Overcoming the GeneratorBottleneck
abstract: The problem of testing program correctness has received considerable attention in computer science. One approach to this problem is the notion of self-testing programs \cite{BlumLubyRubinfeld}. Self-testing usually becomes more costly in the case of testing multivariate functions. In this paper we present efficient methods for self-testing multivariate linear functions. We then apply these methods to several multivariate linear problems to construct efficient self-testers.

title: A Note on Natural Creative Sets and Goedel Numberings

abstract: Creative sets (or the complete recursively enumerable sets) play an important role in logic and mathematics and they are known to be recursively isomorphic. Therefore, on the one hand, all the creative sets can be viewed as equivalent, on the other hand, we intuitively perceive some creative sets as more "natural and simpler" than others. In this note, we try to capture this intuitive concept precisely by defining a creative set to be natural if all other recursively enumerable sets can be reduced to it by computationally simple reductions and show that these natural creative sets are all isomorphic under the same type of computationally simple mappings. The same ideas are also applied to define natural Goedel numberings.

title: An Analysis of the Total Least Squares Problem
abstract: Totla least squares (TLS) is a method of fitting that is appropriate when there are errors in both the observation vector $b (mxl)$ and in the data matrix $A (mxn)$. The technique has been discussed by several authors and amounts to fitting a "best" subspace to the points $(a^{T}_{i},b_{i}), i=1,\ldots,m,$ where a^{T}_{i} is the i-th row of A. In this paper a singular value decomposition analysis of the TLS problem is presented. The sensitivity of the TLS problem as well as its relationship to ordinary least squares regression is explored. Aan algorithm for solving the TLS problem is proposed that utilizes the singular value decomposition and which provides a measure of the underlying problem's sensitivity.

title: The Use of Negative Curvature in Minimization Algorithms
abstract: IN this paper we examine existiing algorithms for minimizing a nonlinear function of many variables which make use of negative curvature. These algorithms can all be viewed as modified versions of Newton's method and their merits and drawbacks are discussed to help identify new and more promising methods. The algorithms considered include ones which compute and search along nonascent directions of negative curvature and ones which search along curvi-linear paths generated by these directions and descent directions. Versions of the Goldfield-Quandt-Trotter method, or equivalently, methods based upon a trust region strategy, and gradient path methods are also considered. When combined with the numerically stable Bunch-Parlett factorization of a symmetric indefinite matrix the latter two approaches give rise to new, and what appears to be, efficient and robust minimization methods which can take advantage of negative curvature when it is encountered. Several suggestions are made for further research in this area.

title: Languages Simultaneously Complete for One-Way and Two-Way Log-Tape Automata
abstract: In this paper we study languages accepted by nondeterministic $\log n$-tape automata which scan their input only once and relate their computational power to two-way, $\log n$-tape automata. We show that for the one-way, $\log n$-tape automata the nondeterministic model (1-NL) is computationally much more powerful than the deterministic model (1-L); that under one-way, $\log n$-tape reductions there exist natural complete languages for these automata and that the complete languages cannot be sparse. Furthermore, we show that any language complete for nondeterministic one-way $\log n$-tape automata (under 1-L reductions) is also complete for the computationally more powerful nondeterministic two-way, $\log n$-tape reductions. Therefore, for all bounds $T(n),T(n \geq \log n$, the deterministic and nondeterministic $T(n)$-tape bounded computations collapse if the nondeterministic one-way $\log n$-tape computations can be carried out by two-way deterministic $\log n$-tape automata.

title: Sparse Complete Sets for NP: Solution of a Conjecture by Berman and Hartmanis
abstract: In this paper we show that if NP has a sparse complete set under many-one reductions, then P=NP. The result is extended to show that if NP is sparse reducible, then P=NP. The main techniques of this paper generalize the NP recognizer for the complement of a sparse complete set with census function to the case where the census function is not known (c.f. [HM]), then a many-one reduction of this language to the sparse set permits a polynomial time bounded tree search as in [B], [F], or [MP]. Even without actual knowledge of the census, the algorithm utilizes the properties of the true census to decide membership in SAT in polynomial time.

title: Effective Information Retrieval Using Term Accuracy
abstract: The performance of information retrieval systems can be evaluated in a number of different ways. Much of the published evaluation work is based on measuring the retrieval performance of an average user query. Unfortunately, formal proofs are difficult to construct for the average case. In the present study, retrieval evaluation is based on optimizing the performance of a specific user query. The concept of query term accuracy is introduced as the probability of occurrence of a query term in the documents relevant to that query. By relating term accuracy to the frequency of occurrence of the term in the documents of a collection it is possible to give formal proofs of the effectiveness with respect to a given user query of a number of automatic indexing systems that have been used successfully in experimental situations. Among these are inverse document frequency weighting, thesaurus construction, and phrase generation.

title: Specification and Verification of Communication in Parallel Systems
abstract: This thesis develops a verification theory for systems of parallel processes communicating with one another by sending messages. The goal is independent specification of processes in a system, so that the system can be verified from the specifications of its component processes. A process is regarded as a generator of a formal language called its communication language. A specification is written as a first order predicate calculus formula about this formal language. Processes are verified by including assertions in them and proving that the assertions hold, much as is done for sequential programs. An important aspect of the work is its treatment of non-determinism and its effect on the termination, non-termination, and deadlock properties of systems and processes. It is argued that non-determinism should be curtailed if specifications are to accurately reflect the specifier's wishes. Rules relating assertions and statements are similar to those used in Floyd-Hoare logic. However, we deal here with both partial correctness, sometimes called safety in the literature, and liveness, which is a concept analgous to termination of sequential programs. Justification of liveness assertions takes advantage of statements that occur both before and after the assertion, introducing a new kind of proof rule which we prove is correct.

title: The Fundamental Theorem of Arithmetic in PL/CV2
abstract: This document is a section of formal elementary number theory leading up to a complete proof of the fundamental theorem of arithmetic. On the way to this result a large number of simple facts about integer division, prime numbers, greatest common divisors, and the product function, $\prod_{i=1}^{m}a(i)$, are developed. The entire section is written in the formal logic of PL/CV2, and the proof was checked by the PL/CV2 Proof Checker on an IBM 370/168. Readers familiar with the syntax of a high level programming language, like PL/I, and accustomed to highly symbolic mathematical proofs should be able to read this document as a specimen of extremely formal and rigorous mathematics. The following remarks about PL/CV2 notation will simplify reading. 1. The *PROCESS line indicates the beginning of PL/I executable text, the *THEOREM line indicates the beginning of purely declarative text. 2. All proof text is written between PL/I comment delimiters of the form /*/...*/ or /#...#/ depending on context. 3. For the built-in PL/I functions ABS, MOD, SIGN, MAX, MIN, EXP, DIVISION (/) only the properties of the functions are listed, in Section 0 called BUILT-IN FUNCTIONS. No proofs of these properties are supplied (because the operations are provided by the system). Thus proved propositions appear starting in Section 1 (at line 0036). 4. In the listing the negation sign is written ^, thus B ^= 0 reads "B not equal to zero". The PL/I symbol for "or" is the vertical bar, thus line 0037 TRI : B less than 0|B=0|B greater than 0 is labeled by TRI (for trichotomy) and means B is less than or equal to 0 or greater than 0. The justification... BY ARITH... indicates that the conclusion follows from simple arithmetic reasoning, provided by the system, from the list of hypotheses. 5. Every PL/CV2 procedure, such as LOG at line 0049, begins with an ASSUME statement, telling what is

assumed about the input, and with an ATTAIN statement telling what will be proved about it. Also every procedure is proved to terminate. In the case of recursive procedures, the termination proof begins with the line ARBITRARY (integer variable) WHERE (conditon) (see line 0053). It is proved that this integer variable decreases on any recursive call.

title: A Constructive Alternative to Axiomatic Data Type Definitions
abstract: Many computer scientists advocate using axiomatic methods (such as algebraic specification) to specify a program data domain - the universe of abstract data objects and operations manipulated by a program. Unfortunately, correct axiomatizations are difficult to write and to understand. Furthermore, their non-constructive nature precludes automatic implementation by a language processor. In this paper, we present a more disciplined, purely constructive alternative to axiomatic data domain specification. Instead of axiomatizing the program data domain, the programmer explicitly constructs it by using four type construction mechanisms: constructor generation, union generation, subset generation, and quotient generation. These mechanisms are rich enough to define all of the abstract data objects that programmers commonly use: integers, sequences, trees, sets, arrays, functions, etc. In contrast to axiomatic definitions, constructive definitions are easy to write and to understand. An unexpected advantage of the constructive approach is a limited capacity to support non-deterministic operations. As an illustration, we define a non-deterministic “choose” operation on sets.

title: Permutations and the APL Grade Down Function
abstract: The APL gradeup (gradedown) function (denoted by $\uparrow \{respectively \downarrow \}$) aapplied to a vector $v \in R^{n}$ `grades' the elements of v in ascending (descending) order. (Among equal elements of v the ranking is determined by their position). For example, if $v=(2.3,4.7,6.8,0.6,3.7,4.7)$ then $\uparrow v$ is (4,1,5,2,6,3) and $\downarrow v$ is (3,2,6,5,1,4). An immediate consequence of the versatility of this functional form is that the expression $v[\uparrow v] (v[\downarrow v])$ `sorts' the elements of v in ascending (descending) order. The question of characterizing all vectors $v \in R^{n}$ such that $\uparrow v=v$ was answered in a paper by Cooper, Best and Kennedy [see Cooper, et al.(1)]. The results there are essentially determined by scrutinizing the selection property of $\uparrow v$; that is, if $v=(x_{1}, x_{2},\ldots, x_{n})$ then $\uparrow v$ can be visualized as the unique permutation $P \in S_{n}$ such that $x_{P(1)},x_{P(2),\ldots,x_{P(n)}$ is a list of the elements f v in ascending order. Two straightforward consequences of this interpretation are: 1) if $P \in S_{n}$, then $\uparrow P$ is the inverse of P and 2) the `fixed' points of the mapping $\uparrow$ are precisely the involutions of S_{n}. IN this note we continue this investigation for the gradedown function and also resolve the open questions posed in that paper.

title: A Classroom Note on Topological Ordering
abstract: A partially ordered set (poset) is a pair (S,R) where S is a nonempty set and R is a reflexive, antisymmetric, transitive relation on S. (Equivalently, a pair (S,R') where R' is an irreflexive, transitive relation on S.) Unless otherwise stated the second definition will be the one used in this discussion. (S,R) is a chain if R is a total order on S, that is, given any pair a, b in S, either (a,b) or (b,a) is in R. The notion of embedding a poset in a complete lattice is a well known lattice theoretic result. [see Foulis(1)] In this sequel we consider a special case of that result; namely, the embedding of a poset in a chain. Although the proof in the finite case suggests an intuitively obvious constructive algorithm [see Kahn(2)] it was only recently that an `optimal' solution was discovered which can be implemented in linear time. [see Knuth(3)]. The proof in the infinite case first appeared in print in a paper by Szpilrajn. [see Szpilrajn(4)]. In this presentation the proof in the infinite case is a reasonably `clean' and straightforward application of Zorn's lemma which can be readily understood by the average undergraduate.

title: Proof Rules for Communicating Sequential Processes
abstract: This thesis presents proof rules for an extension of Hoare's Communicating Sequential Processes (CSP). CSP is a notation for describing processes that interact through communication, which provides the sole means of synchronizing and passing information between processes. A sending process is delayed until some process is ready to receive the message; a receiving process is delayed until there is a message to be received. It is this delay that provides synchronization. A proof of a program is with respect to pre- and postconditions. A proof of weak correctness shows that execution of the program beginning in a state satisfying the precondition terminates in a state satisfying the postcondition, provided deadlock does not occur. A proof of strong correctness, in addition, shows that deadlock cannot occur. A proof of weak correctness has three stages: a sequential proof, a satisfaction proof, and a non-interference proof. A sequential proof reflects the effects of a process running in isolation. A satisfaction proof combines sequential proofs of processes, reflecting the message passing and synchronization aspects of communication. A non-interference proof shows that no process affects the validity of the proof of another process. The introduction of the satisfaction proof and our symmetric treatment of send and receive are important aspects of this thesis. By treating send and receive on an equal basis, we simplify our rules and allow the inclusion of send in guards. A sufficient condition for freedom from deadlock is given that depends on the proof of weak correctness; this is used to prove strong correctness. In general, freedom from deadlock can be very hard to check. Therefore, we derive special cases in which we can reduce the work needed to verify that a program is free from deadlock. We also present an algorithm for globally synchronizing processes; that is, each process can recognize that all processes are simultaneously in a given state. It works by recognizing a special class of deadlock. Having this algorithm allows us to modify programs that deadlock when the postcondition is established, so that they terminate normally.

title: Floating-Point Arithmetic and Program Correctness Proofs
abstract: This thesis develops tight upper and lower bounds on the relative error in various schemes for performing floating-point arithmetic, proposes axioms for characterizing the significant properties embodied by these schemes, and gives examples to illustrate how these axioms may be used to reason about the correctness of floating-point programs. Three addition schemes are considered: (1) chopped addition, (2) addition with both pre and post-adjustment rounding, and (3) addition with pre-adjustment chopping and post-adjustment rounding. Schemes for performing both rounded and chopped multiplication and division are also considered. Our tight bounds are consistent with the commonly held opinion that a binary base minimizes the maximum relative errors in floating-point arithmetic. Also, these bounds show that one guard digit is optimal for minimizing the maximum relative errors in chopped addition. The bounds derived for each of the addition schemes considered are as tight as possible. One guard digit and two guard bits are shown to be sufficient to round the result of an exact addition to the nearest floating-point number. We show how this scheme can be implemented using a single post-adjustment shift, no rounding overflow, and (for certain implementations) requiring no more time than an addition that chops instead of rounds. Two approaches are considered for axiomatizing floating-point arithmetic. In one approach, a set of floating-point numbers is associated with each floating-point expression, and the assignment statement is modeled as a nondeterministic selector of one of the members in the set. In the alternative approach, the floating-point operations are modeled in terms of two cropping functions whose significant properties are characterized by a small set of axioms. In both cases, the axioms characterizing floating-point arithmetic are used with Dijkstra's weakest pre-condition calculus to provide an axiomatic framework for reasoning about floating-point programs. Finally, the commom practice of modelling the floating-point operations by a single function that chops or rounds the result of the corresponding exact operation is shown to be invalid for many implementations of floating-point arithmetic.

title: Parallel Computations in Information Retrieval
abstract: Conventional information retrieval processes are largely based on data movement, pointer manipulations and integer arithmetic; more refined retrieval algorithms may in addition benefit from substantial computational power. In the present study a number of parallel processing methods are described that serve to enhance retrieval services. In conventional retrieval environments parallel list processing and parallel search facilities are of greatest interest. In more advanced systems, the use of array processors also proves beneficial. Various information retrieval processes are examined and evidence is given to demonstrate the usefulness of parallel processing and fast computational facilities in information retrieval.

title: The Ellipsoid Method: A Survey
abstract: IN February 1979 a note by L.G. Khachiyan indicated how an ellipsoid method for linear programming can be implemented in polynomial time. This result has caused great excitement and stimulated a flood of technical papers. Ordinarily there would be no need for a survey of work so recent. The current circumstances are obviously exceptional. Word of Khachiyan's result has spread extraordinarily fast, much faster than comprehension of its significance. A variety of issues have in general not been well understood, including the exact character of the ellipsoid method and of Khachiyan's result on polynomiality, its practical significance in linear programming, its implementation, its potential applicability to problems outside of the domain of linear programming, and its relationship to earlier work. Our aim here is to help clarify these important issues in the context of a survey of the ellipsoid method, its historical antecedents, recent developments, and current research.

title: Polynomial-Time Algorithms for Permutation Groups
abstract: A permutation group on n letters may always be represented by a small set of generators, even though its size may be exponential in n. We show that it is practical to use such a representation since many problems such as membership testing, equality testing, and inclusion testing are decidable in polynomial time. In addition, we demonstrate that the normal closure of a subgroup can be computed in polynomial time, and that this procedure can be used to test a group for solvability. We also describe an approach to computing the intersection of two groups. The procedures and techniques have wide applicability and have recently been used to improve many graph isomorphism algorithms.

title: Optimal Conditioning in the Convex Class of Rank Two Updates
abstract: Davidson's new quasi-Newton optimization algorithm selects the new inverse Hessian approximation H at each step to be the "optimally conditioned" member of a certain one-parameter class of rank two updates to the last inverse Hessian approximation H. In this paper, we show that virtually the same goals of conditioning can be achieved while restricting H to the convex class of updates. We therefore suggest that Davidson's algorithms using optimal conditioning, restrict the choice of H to members of the convex class.

title: Language Features for Process Interaction
abstract: Language for parallel programming should meet four goals: expressiveness, reliability, security, and verifiability. This paper presents a set of language features for describing processes and process interaction, gives examples of their use, and briefly discusses their relation to the goals. Two constructs, resources and protected variables, are introduced as the mechanisms for describing interaction. Resources are extensions of the monitor concept of Hoare; protected variables are global variables which can only be accessed by one process at a time. Two types of access control are introduced: restrictions on scope rules for static access, and capabilities for dynamic access. Examples include the interface to machine devices, files and virtual devices, device scheduling, device reservation, and buffer allocation.

title: Information Retrieval in the Business Environment
abstract: This paper outlines a possible approach to the use of advanced information storage and retrieval techniques for business correspondence. The present situation in the Office Automation field is surveyed, and the role of information retrieval is an integrated office information system is discussed. Business letter

characteristics that might be useful for analysis and retrieval are described. The idea of a generalized business thesaurus containing standard phrases and locutions as well as synonyms and index phrases is presented. A technical solution to the analysis, storage and retrieval of business letters based on the concepts from the SMART-system is outlined. A description of the experiments performed so far follows. These include decomposition, analysis, storage, automatic classification and utilization of inter-letter references. The results from the experiments show that the use of automatic indexing and retrieval in the office is feasible and provides a viable alternative to existing manual business files. In conclusion, several future experiments are outlined.

title: Reversal-Bounded Computations
abstract: IN computations by abstract computing devices such as the Turing machine, head reversals are required for searching the input or retrieving intermediate results. Hence the number of head reversals is a measure of the complexity of a computation. This thesis is a study of reversal-bounded computation on three models of abstract computing devices. The first model is the 1-tape Turing machine with finite bounds on head reversals. It is known that such machines recognize exactly the regular sets so that for recognition purposes, reversals can be eliminated entirely. For transduction purposes, that is, if an output is expected on the tape, a single reversal suffices. Hence these machines are most appropriately called finite automata. Clearly they are among the weakest possible computing devices, and many decision problems about them are solvable. We use this fact and a very simple input-output encoding scheme to obtain greatly simplified proofs of the decidability of some weak mathematical theories, including the weak monadic second-order theory of one successor and Presburger arithmetic. Similar techniques yield linear size bounds as well as linear time complexity bounds (on the multitape Turing machine model) for functions definable in Presburger arithmetic. As corollaries, we find applications in linear diophantine systems and linear integer programming. The second model is the multicounter machine with general bounds on counter reversals. By relating counter reversal to time and space, we show that recursiveness of reversal bounds implies recursiveness of the sets accepted. For bounds that are at least linear, counter reversal is polynomially equivalent to Turing machine time in both the deterministic and the nondeterministic cases. This result leads to a general deterministic reversal hierarchy and a natural formulation fo the P=?NP question on the multicounter machine model. It also suggests that on every reasonable universal computing model, there is a "natural" complexity measure that is polynomially equivalent to Turing machine time. For reversal bounds that grow more slowly than $n^{1/2}$, we show that the nondeterministic 2-way reversal complexity class is not closed under complementation and strictly includes the corresponding deterministic class. In contrast, the analogous questions are open for 2-way 2-tape Turing machines with logarithmic space bounds. Finally, we consider finite bounds on counter reversals. For both the 1-way and the 2-way models, we obtain very sharp upper bounds on the Turing machine time and space complexity of the languages accepted. In the 1-way case, we present a unified account of the known results, interspersed with our contributions, which include (1) equivalence to 1-way simple multihead finite automata, (2) an easy technique for proving nonrecognizability, (3) an abstract characterization of the power of finite reversal-bounded counters, and (4) an application to the theory of program schemes. Lastly, we consider finite reversal-bounded multitape finite automata. We show that over a single-letter alphabet, the languages accepted are exactly the unary encodings of Presburger relations. This result holds whether the model is determinisitic or nondeterministic, and even if it is augmented with, for example, finite reversal-bounded counters and an unrestricted pushdown store, or if the reversals are restricted to rewinds, that is, instructions that simultaneously position all heads at the beginnings of their respective tapes. For both deterministic and nondeterministic rewind automata, we

establish exhaustive hierarchies based on the finite number of rewinds. When restricted to a single-letter alphabet, the deterministic hierarchy stands but the nondeterministic one collapses.

title: Detecting Distributed Termination When Processors Can Fail
abstract: A collection of protocols to facilitate detection of the termination of a computation on a distributed system are developed. Communication is assumed to be accomplished by use of asynchronous broadcasting. It is argued that this is a reasonable assumption for a distributed system in light of advances in local networking. The protocols presented are all robust with respect to processor failures. They differ in their requirements - some make heavy use of the communications network at the end of a computation, while others spread the communications cost out through the computation. Problems of restarting failed processors are also addressed.

title: Optimal-Time Incremental Semantic Analysis for Syntax-Directed Editors
abstract: Attribute grammars permit the specification of static semantics in an applicative and modular fashion, and thus are a good basis for syntax-directed editors. Such editors represent programs as as attributed trees, which are modified by operations such as subtree pruning and grafting. After each modification, a subset of attributes, AFFECTED, requires new values. Membership in AFFECTED is not known a priori; this paper presents an algorithm that identifies attributes in AFFECTED and recomputes their values. The algorithm is time-optimal, its cost is proportional to the size of AFFECTED.

title: A Logic for Correct Program Development
abstract: Existing verification technology, though theoretically adequate, is not directly applicable to the construction of large software systems. This thesis explores the view that reasoning about code is not the proper paradigm for correct program development. Instead, specifications should be the objects of study and a logic should be formulated for constructively proving that specifications have acceptable implementations; from these proofs code may be extracted. Thus, constructive existence proofs become the programmer's main concern, while executable text is seen as a valuable by-product of correct reasoning which cannot be produced from incorrect reasoning. The thesis captures this view of program development in a logic for the formal refinement of specifications. Specifications are written in an imperative notation of generalized assignment; they allow calculations in integer arithmetic and finite set theory. Classical reasoning techniques are shown inconsistent in this domain (where propositions may claim the constructive existence of programs), hence an alternative logic is developed based on intuitionistic reasoning. Proofs in this constructive refinement logic are trees, stylistically similar to those of Gerhard Gentzen's sequent calculus. It is argued that while linear proofs are appropriate when reasoning is developed and presented on paper, hierarchical proofs are appropriate when reasoning is developed and presented with machine aid. A mechanism is described that extracts correct codes from valid proofs; its existence assures the consistency of the logic. Finally, several code optimization techniques are examined and applied to code extracted from sample proofs. The thesis concludes with a discussion of the expounded view of correct program development, suggestions for a program development system based on this view, and a look at the numerous research problems remaining in this area.

title: Simple Error Recovery Scheme for Optimized LR-Parsers
abstract: A new, simple and effective method for syntactic error recovery in optimized (reduced) LR-parsers is presented. This method, called the Simple Recovery and Correction scheme, is phrase oriented and performs local and some form of global contect correction. The error handling mechanism is driven by information obtainable from an LR-parser decision table. The formal basis for the method is the concept of synchronizing triple. A theoretical characterization of synchronizing triples is given and algorithms for direct extraction of recovery control information are presented. As a part of the SRC scheme a simplified method for the organization of LR-parser forward moves is introduced. In the last part of the paper the performance of the SRC scheme is illustrated in a specific case and implementation problems are discussed.

title: A Comparison of Search Term Weighting: Term Relevance vs. Inverse Document Frequency
abstract: The term relevance weighting method has been shown to produce optimal information retrieval queries under well-defined conditions. The parameters needed to generate the term relevance factors cannot unfortunately be estimated accurately in practice; furthermore, in realistic test situations, it appears difficult to obtain improved retrieval results using the term relevance weights over much simpler term weighting systems such as, for example, the inverse document frequency weights. It is shown in this study that the inverse document frequency weights and the term relevance weights are closely related over a wide range of the frequency spectrum. Methods are introduced for estimating the term relevance weights, and experimental results are given comparing the inverse document frequency with the estimated term relevance weights.

title: Determining Logical Dependency in a Decision Procedure for Equality
abstract: Several existing program verification and automated prooff systems make use of similar decision procedures for equality ([Krafft 1978], [Nelson and Oppen 1977] and [Downey, Sethi and Tarjan 1980]). The general method used by these algorithms has been named congruence closure. Given two expressions on uninterpreted function symbols, a congruence closure algorithm determines whether the expressions can be deduced to be equal from a set of previously asserted equalities. The existing congruence closure algorithms do not provide any indication of which previously asserted equalities were required in the deduction. In this paper, we describe an extension to one version of congruence closure. When two expressions are equal, the new algorithm can provide a certificate of their equality: a list of prevviously asserted equalities from which the queried equality can be deduced. This list is minimal, in the sense that if any equality iss removed from the list, the queried equality can no longer be deduced. The running time to produce the certificate is almost-linear in the size of the list.

title: Generalizing the LINPACK Condition Estimator
abstract: Two generalizations of the Cline-Moler-Stewart-Wilkinson "LINPACK" condition estimator are described. One generalization combines the LINPACK notion of "look-ahead" with a new feature called "look-behind" that results in a more flexibly chosen right-hand side. The other generalization is a "divide-and-conquer" scheme that involves estimating the condition of certain principal submatrices whose dimension repeatedly doubles. Both generalizations require that maximization of simple objective functions. When seeking an L_{1} condition estimate, these functions are convex while inthe L_{2} case they are quadratic. All the algorithms considered appear to be at least as reliable as the LINPACK estimator and are equally efficient.

title: A Note on the Complexity of Goedel Numberings and Isomorphisms
abstract: Some problems involved in looking at recursive function theory and thinking about the complexity of computations are discussed. Complexity classes of Goedel numberings are studied where a Goedel numbering is in a given complexity class if every other Goedel numbering can be translated into it by functions ina given complexity class. In particular, we look at the class of numberings that can be trnslated into by polynomial time mappings (GNP) and the class that can be translated into by linear bounded automation mappings (GNLBA). It is shown that polynomial time isomorphisms and LBA computable isomorphisms between two Goedel numberings relate the complexity of the syntax of the numberings. Since the classes GNP and GNLBA contain Goedel numberings with arbitrarily hard syntax, not all members of these classes are isomorphic by polynomial time or LBA mappings. LBA computable isomorphisms can be found between members of GNLBA whose syntax is LBA recognizable. A similar result holds for polynomial time isomorphisms and GNP if P=NP.

title: AVID: A system for the Interactive Development of Verifiably Correct Programs
abstract: The AVID system is designed to Aid Verification through the techniques of Interactive program Development. AVID continues the work in programming logics begun at Cornell University in 1975. It provides a syntax-directed editing environment for the development by stepwise refinement of programs and proofs in the PL/CV2 programming logic. AVID is another step in the continuing effort to provide methods and software tools for developing correct programs. AVID contains a number of important contributions to the area of program/proof development. To allow the full power of the AVID verification facilities to be applied to programs developed by stepwise refinement, we created a new program construct, called an ATTAIN block, that formalizes the concept of a refinement level. This construct allows the independent verification of different refinement levels, and thus of partially developed programs. Using this construct, AVID can guarantee that the refinement in a top-down development actually implements its high-level specification. AVID is the first system to support the interactive display of logical dependency in proofs. We have developed a new algorithm, built on the congruence closure method for deciding the theory of equality, that efficiently determines logical dependency within this theory. This algorithm is independent of the AVID system, and has potential applications wherever the congruence closure method is used. AVID also contains some significant contributions to the area of syntax-directed editor design. AVID makes use of a standard, powerful, and widely available screen-oriented editor as its user interface. The system design gives a strategy for the incorporation of other powerful editors into syntax-directed development systems. AVID is also the first system to make extensive use of derived nonterminals to avoid redundant specification and to guide the user in developing his proof. Perhaps AVID's most important contribution is its demonstration of the feasibility of a system to support and enforce the development by stepwise refinement of provably correct programs. For programs that must be correct, this approach may be one of the most promising. One final contribution of the AVID project is the system itself as a base for future research. The modular design of the AVID system and its facilities for the high-level description of AVID language constructs make the system easy to modify and to build on. There are already several projects planning to use AVID in this fashion.

AVID has been implemented on a DEC VAX 11/780 under the Berkeley UNIX operating system. The current version of the system, which supports the development and verification of the predicate calculus portion of PL/CV2, consists of approximately 20,000 lines of C language source code. When running on the VAX, the current system requires 230K bytes of memory. A version of the system suitable for distribution is expected to be available by January 1982.

title: Rendezvous Primitives for Operating System Design
abstract: A well chosen, comprehensive set of kernel primitives is essential for the construction of higher levels of a computer's operating system. In particular, although many solutions to the classical operating system problems of interprocess synchronization and communication have been proposed in the past, difficulties with destination naming and language construct symmetry have continued to mar most proposed solutions. This thesis proposes a set of primitives, the Rendezvous primitives, that form the kernel of an operating system. It is argued that the Rendezvous primitives constitute a reasonable and practical set of

operations on which to base an operating system. The Rendezvous primitive itself is presented as a solution to the interprocess synchronization and communication problems. A rendezvous occurs when two processes synchronize and subsequently exchange messages. Rendezvous is symmetric, in that processes that wish to communicate both use the same primitive; and processes invoke Rendezvous with class designations, not procedure names. Rendezvous is presented within the context of the other primitives, which support the restriction of access to Rendezvous, process creation and destruction, process scheduling, and stack resource management. A comparison of Rendezvous and existing primitives and language constructs to solve interprocess synchronization and communication is made. The full syntax and semantics of the Rendezvous primitives are presented, along with a discussion of their design rationale. The Crossbar Switch, a generalized virtual device interconnection and reconfiguration scheme, is presented as an example of the use to which the Rendezvous primitives might be put. A high level program description of the Crossbar Switch is presented as well. The thesis concludes with a description of the implementation of the Rendezvous kernel on a DEC PDP 11/60. The kernel code is given in an appendix.

title: Efficient Generation of Memory Reference Strings Based on the LRU Stack Model of Program

Behaviour
abstract: We consider the problem of generating memory reference strings that are to be used instead of real program address traces with the generator based on the Least-Recently-Used Stack Model (LRUSM) of program behaviour. A method to transform the stack distance probability mass function that drives the generator is proposed which results in memory reference strings that are a fraction of theoriginal string length while preserving most of its essential performance characteristics. The reduced string can be processed in much the same way as the original string for virtual memory studies that deal with memory sizes greater than k, the parameter of the transformation.

title: User Recovery and Reversal in Interactive Systems
abstract: Interactive systems, such as editors and program development environments, should be explicitly support recovery - facilities that permit a user to reverse the effects of past actions and to restore an object to a prior state. A model for interactive systems is presented that allows recovery to be defined precisely and user and system responsibilities to be delineated. Various implementation techniques for supporting recovery are described. Application of a general recovery facility to support reverse execution is discussed. A program development system (called COPE) with extensive recovery facilities, including reverse execution, is described. Keywords: recovery, reverse execution, undo, checkpoint, editor, programming environments.

title: Axiomatic Verification to Enhance Software Reliability
abstract: Techniques that facilitate the design of reliable software are described. Two distinct phenomena that can cause execution of a program to deviate from its specifications are considered. The first is the failure of the computing system on which the program is running. When this occurs, the system might not be capable of following the instructions specified by the program. The second phenomenon is that the program is written so that it will not execute consistently with its specifications, even on a failure-free computing system. A methodology is presented for designing programs that can cope with failures in the underlying system. It is based on the notion of a fail-stop processor - a processor with well-defined failure mode operating characteristics. Axiomatic program verification techniques are extended for use in developing provably correct programs for such processors. The problem of meeting response time goals in light of failures is discussed. Lastly, the problem of implementing processors that, with high probability, behave like fail-stop processors is addressed. Programming logics have already been developed to reason about sequential programs, and parallel programs that use shared memory or synchronous message-passing. That work is extended to facilitate reasoning about programs that use asynchronous message-passing. Two benefits accrue from this. The obvious one is that partial correctness proofs can be written for concurrent programs that use such primitives. This allows such programs to be understood as predicate transformers, instead of by contemplating all possible execution interleavings - often an intractible task. The other benefit is that these proof rules and their derivation shed light onto how this interference can be controlled. In particular, disciplines that make asynchronous message-passing primitives simple and safe to use are explored. A partial correctness proof of the two-phase commit protocol illustrates the application of the new techniques. This protocol, widely used in database applications, ensures that a specified action is performed either at all sites in a distributed system, or at no site, despite failures.

title: On the Movement of Robot Arms in Two Dimensional Bounded Regions
abstract: The classical mover's problem is the following: can a rigid object in 3-dimensional space be moved from one given position to another while avoiding obstacles? It is known that a more general version of this problem involving objects with movable joints is PSPACE complete, even for a simple tree-like structure moving in a 3-dimensional region. In this paper, we investigate a 2-dimensional mover's problem in which the object is a robot arm with an arbitrary number of joints. In particular, we give a polynomial time algorithm for moving an arm confined within a circle from one given configuration to another. We also give a polynomial time algorithm for moving the arm from its initial position to a position in which the end of the arm reaches a given point within the circle. Keywords: robotics, manipulators, mechanical arms,

algorithms, polynomial time.

title: A Method for Solving Certain Graph Recognition and Optimization Problems, with Applications to Perfect Graphs
abstract: A polynomial time membership test and solutions to the minimum coloring and maximum weight clique and stable set problems are given for certain families of graphs. In particular, it is shown that for any arbitrary hereditary family of graphs, these problems can be solved quickly for the entire family whenever they can be solved quickly for the clique cutset free members of the family. If the graphs in the family are perfect, then a similar statement holds for the mimimum weight clique and stable set problems. These results are obtained by applying a polynomial time algorithm for determining whether a graph has a clique cutset. Several questions of Gavril concerning "clique separable" perfect graphs are answered, and a polynomial time recognition algorithm for Gallai's "i-triangulated" perfect graphs is given. Keywords: graph algorithms, cliques, stable sets, perfect graphs, clique separable graphs, i-triangulated graphs.

title: Determining the Last Process to Fail
abstract: A total failure occurs whenever all processes cooperatively executing a distributed task fail before the task's completion. A frequent prerequisite for recovery from a total failure is the identification of the last group (LAST) of processes concurrently failing. Herein, we derive necessary and sufficient conditions for computing LAST from the local failure data of recovered processes. These conditions are easily translated into decision procedures for LAST membership using either complete or incomplete failure data. The choice of failure data itself is dictated by two requirements: (1) it can be cheaply maintained, and (2) maximum fault-tolerance is afforded in the sense that the expected number of recoveries required for identifying LAST is minimized.

title: Dual Variable Metric Algorithms for Constrained Optimization
abstract: We present a class of algorithms for solving constrained optimization problems. In the algorithm non-negatively constrained quadratic programming subproblems are iteratively solved to obtain estimates of Lagrange multipliers and with these estimates a sequence of points which converges to the solution is generated. To achieve a superlinear rate of convergence the matrix appearing in the subproblem is required to be an approximate inverse of the Hessian of the Lagrangian. Some well-known variable metric updates such as the BFGS update are employed to generate the matrix and the resulting algorithm converges locally

with a superlinear rate. When the penalty Lagrangian developed by Hestenes, Powell and Rockafellar is incorporated in the algorithm, it turns out to be closely related to the recently developed the method of multipliers. Unlike the method of multipliers, our algorithm possesses a superlinear rate of convergence even without requiring a penalty parameter goint to infinity and therefore avoids the numerical instability so caused.

title: A Survey of Some Recent Results on Computational Complexity in Weak Theories of Arithmetic
abstract: In spite of the fact that a great deal of effort has been expended trying to prove lower bounds for algorithms and trying to solve the P = NP question, only limited progress has been made. Although most computer scientists remain convinced that solutions will be found, others (Hartmanis and Hopcroft, Fortune, Leivant and O'Donnell and Phillips) have questioned the adequacy of Peano arithmetic for computer science. This uncertainty has only been increased by the recent work of Paris and Harrington, showing that certain simple, finistic, combinatorial statements are in fact independent of Peano Arithmetic. In this paper we survey complexity theoretic statements that are known to be independent of arithmetic theories. In addition, we survey recent results analyzing the arithmetic quantifier structure of computational problems. Keywords: Independence results, NP=?coNP, P=?NP, Peano arithmetic.

title: Software for Estimating Sparse Jacobian Matrices
abstract: In many nonlinear problems it is necessary to estimate the Jacobian matrix of a nonlinear mapping F. In large scale problems the Jacobian of F is usually sparse, and then estimation by differences is attractive because the number of differences can be small compared to the dimension of the problem. For example, if the Jacobian matrix is banded then the number of differences needed to estimate the Jacobian matrix is, at most, the width of the band. In this paper we describe a set of subroutines whose purpose is to estimate the Jacobian matrix of a mapping F with the least possible number of function evaluations.

title: The Efficient Implementation of Very-High-Level Programming Language Constructs
abstract: An investigation is made into efficiently-implementable very-high-level programming language

constructs. In a manner analogous to ALGOL 60's abstraction away from GOTO's, an abstract replacement for pointers (the path) is proposed. The use of paths instead of pointers in unshared recursive data structures greatly simplifies the process of reasoning about programs. The existence of an efficient implementation of paths makes their use palatable as well as desirable. Also investigated is the integration of paths with existing very-high-level programming language implementation techniques, such as hash-consing. Several real-time programs in Pure LISP are presented. Building on the foundation of a real-time queue and a real-time double-ended queue, a real-time implementation of paths is given. This leads to the surprising negative result that the addition of paths does not increase the "power" of Pure LISP.

title: Finding Repeated Elements
abstract: Two algorithms are presented for finding the values that occur more than $n \div k$ times in array b[O:n-1]. The second algorithm requires time $O(n \log(k))$ and extra space $O(k)$. We prove that $O(n \log(k))$ is a lower bound on the time required for any algorithm based on comparing array elements, so that the second algorithm is optimal. As special cases, determining whether a value occurs more than $n \div 2$ times requires linear time, but determining whether there are duplicates - the case $k=n$ - requires time $O(n \log(n))$. The algorithms may be interesting from a standpoint of programming methodology; each was developed as an extension of an algorithm for the simple case $k=2$.

title: A Separator Theorem for Graphs of Bounded Genus
abstract: Many divide-and-conquer algorithms on graphs are based on finding a small set of vertices or edges whose removal divides the graph roughly in half. Most graphs do not have the necessary small separators, but some useful classes do. One such class is planar graphs: If we can draw an n-vertex graph on the plane, then we can bisect it by removing $O(\sqrt{n})$ vertices [Lipt79b]. The main result of this paper is that if we can draw a graph on a surface of genus g, then we can bisect it by removing $O(\sqrt{gn})$ vertices. This bound is best possible to within a constant factor. We give an algorithm for finding the separator that takes time linear in the number of edges in the graph, given an embedding of the graph in its genus surface. We discuss some extensions and applications of these results.

title: On the Local Convergence of a Quasi-Newton Method for the Nonlinear Programming Problem
abstract: In this paper we propose a new local quasi-Newton method to solve the equality constrained non-linear programming problem. The pivotal feature of the algorithm is that a projection of the Hessian of the Lagrangian is approximated by a sequence of symmetric positive definitive matrices. The matrix approximation is updated at every iteration by a projected version of the DFP or BFGS formula. We establish that the method is locally convergent and the sequence of x-values converges to the solution at a 2-step Q-superlinear rate.

title: A Note on the Computation of an Orthonormal Basis for the Null Space of a Matrix
abstract: A highly regarded method to obtain an orthonormal basis, Z, for the null space of a matrix A^{T} is the QR decomposition of A, where Q is the product of Householder matrices. In several optimization contexts $A(x)$ varies continuously with x and it is desirable the $Z(x)$ vary continuously also. In this note we demonstrate that the standard implementation of the QR decomposition does not yield an orthonormal basis $Z(x)$ whose elements vary continuously with x. We suggest three possible remedies.

title: Extended Boolean Information Retrieval
abstract: In conventional information retrieval Boolean combinations of index terms are used to formulate the users' information requests. While any document is in principle retrievable by a Boolean query, the amount of output obtainable by Boolean processing is difficult to control, and the retrieved items are not ranked in any presumed order of importance to the user population. In the vector processing model of retrieval, the retrieved items are easily ranked in decreasing order of the query-record similarity, but the queries themselves are unstructured and expressed as simple sets of weighted index terms. A new, extended Boolean information retrieval system is introduced which is intermediate between the Boolean system of query processing and

the vector processing model. The query structure inherent in the Boolean system is preserved, while at the same time weighted terms may be incorporated into both queries and stored documents; the retrieved output can also be ranked in strict similarity order with the user queries. A conventional retrieval system can be modified to make use of the extended system. Laboratory tests indicate that the extended system produces better retrieval output than either the Boolean or the vector processing systems.

title: Hierarchical Replacement Decisions in Hierarchical Stores
abstract: One of the primary motivations for implementing virtual memory is its ability to automatically manage a hierarchy of storage systems with different characteristics. The composite system behaves as if it were a single-level system having the more desirable characteristics of each of its constituent levels. In this paper, we extend the virtual memory concept to within each of the levels of the hierarchy. Each level is thought of as containing two additional levels within it. This hierarchy is not a physical one, but rather an artificial one arising from the employment of two different replacement algorithms. Given two replacement algorithms, one of which has good performance but high implementation cost and the other poor performance but low implementation cost, we propose and analyze schemes that result in an overall algorithm having the performance characteristics of the former and the cost characteristics of the latter. We discuss the suitability of such schemes in the management of storage hierarchies that lack page reference bits.

title: Generating Language-Based Environments
abstract: This thesis concerns the design of interactive, language-based programming environments that use knowledge of a programming language to provide functions based on the structure and meaning of programs. The goal of the research is a system-constructor to enable editors for different languages to be created easily. The most challenging aspect of such a system is the design of the semantic component, because a language-based editor performs static semantic analysis when a program is altered in order to detect erroneous constructions or to prevent illegal modifications. For efficiency, this should be performed incrementally, re-using as much old information as possible; therefore, a major focus of my research concerns a model of editing for which it is possible to perform incremental semantic analysis efficiently. In this model, a program is represented as an attributed tree in which all attributes have consistent values; programs are modified by tree operations such as pruning, grafting, and deriving. After each modification, some of the attributes require new values; incremental semantic analysis is performed by updating attribute values to again make them all consistent. The thesis presents several algorithms for this process that are asymptotically optimal

in time. The chief disadvantage of attribute grammars is that they use large amounts of storage. The thesis discusses three aspects of utilizing storage efficiently in such systems. One way to reduce the amount of storage used is to reduce the number of atttribute values retained at any stage of attribute evaluation. The thesis establishes two results concerning this idea: it presents one algorithm for evaluating an n-attribute tree that never saves more than $O(\sqrt{n}$ attribute values, and it presents a second algorithm that never saves more than $O(\log n)$ attribute values. A second method for reducing the amount of storage is to share the space used for storing attributes whose values are complex data structures; the thesis presents a very general method for such sharing that can be applied to attributes of many types. Finally, the thesis describes how, by restricting the class of attribute grammars, it is possible to reduce the amount of storage overhead required for updating trees in optimal time.

title: Concepts and Notations for Concurrent Programming
abstract: Much has been learned in the last decade about concurrent programming. This paper identifies the major concepts and describes some of the more important language notations for writing concurrent programs. The roles of processes, communication and syhchronization are discussed from both an operational and an axiomatic viewpoint. Language notations for expressing concurrent execution and for specifying process interaction are surveyed. Synchronization primitives based on shared variables and on message passing are described. Finally, three general classes of concurrent programming languages are identified and compared.

title: A Separator Theorem for Chordal Graphs
abstract: Chordal graphs are undirected graphs in which every cycle of length at least four has a chord. They are sometimes called rigid circuit graphs or perfect elimination graphs; the last name reflects their utility in modelling Gaussian elimination on sparse matrices. The main result of this paper is that a chordal graph with n vertices and m edges can be cut in half by removing $O(\sqrt{m})$ vertices. A similar result holds if the vertices have non-negative weights and we want to bisect the graph by weight, or even if we want to bisect the graph simultaneously by several unrelated sets of weights.

title: Automatic Query Formulations in Information Retrieval

abstract: Modern information retrieval systems are designed to supply relevant information in response to requests received from the user population. In most retrieval environments the search requests consist of keywords, or index terms, interrelated by appropriate Boolean operators. Since it is difficult for untrained users to generate effective Boolean search requests, trained search intermediaries are normally used to translate original statements of user need into useful Boolean search formulations. Methods are introduced in this study which reduce the role of the search intermediaries by making it possible to generate Boolean search formulations completely automatically from natural language statements provided by the system patrons. Frequency considerations are used automatically to generate appropriate term combinations as well as Boolean connectives relating the terms. Methods are covered to produce automatic query formulations both in a standard Boolean logic system, as well as in an extended Boolean system in which the strict interpretation of the connectives is relaxed. Experimental results are supplied to evaluate the effectiveness of the automatic query formulation process in practice.

title: A Systolic Architecture for Almost Linear-Time Solution of the Symmetric Eigenvalue Problem
abstract: An algorithm is presented for computing the eigenvalues and eigenvectors of an n x n real symmetric matrix. The algorithm is essentially a Jacobi method implemented on a two-dimensional systolic array of $O(n^{2})$ processors with nearest-neighbor communication between processors. The speedup over the serial Jacobi method is $\Theta(n^{2})$, so the algorithm converges to working accuracy in time $O(nS))$, where S is the number of sweeps (typically $S \leq 10)$. Key Words and Phrases: Eigenvalue decomposition, real symmetric matrices, Hermitian matrices, Jacobi method, linear-time computation, systolic arrays, VLSI, real-time computation.

title: Using $\cal SEEK$ for Multi-Channel Pattern Recognition
abstract: Our work on computerized analysis of the 2-channel, 24-hr electrocardiogram has resulted in the development of multi-channel signal processing systems that learn by observation. In this paper a new tool for implementing such algorithms is described: the pattern recognition language $\cal SEEK$. Programs written in $\cal SEEK$ build a knowledge base containing tree-like data structures, each of which stores acquired information about a particular multi-channel waveform. Input data is interpreted by performing an efficient parallel evaluation of the structures in the knowledge base. Our work is applicable to a wide variety of pattern recognition problems that arise in medical signal processing. The approach is illustrated with examples drawn from ECG analysis.

title: Proofs as Programs
abstract: The significant intellectual cost of programming is for problem solving and explaining and not for coding. Yet, programming systems offer mechanical assistance exclusively with the coding process. Here we describe an implemented program development system, called PRL ("pearl"), that provides automated assistance with the hard part. The program and its explanation are seen as formal objects in a constructive logic of the data domains. These formal explanations can be executed at various stages of completion. The most incomplete explanations resemble applicative programs, the most complete are formal proofs.

title: Estimation of Sparse Hessian Matrices and Graph Coloring Problems
abstract: Large scale optimization problems often require an approximation to the Hessian matrix. If the Hessian matrix is sparse then estimation by differences of gradients is attractive because the number of required differences is usually small compared to the dimension of the problem. The problem of estimating Hessian matrices by diferences can be phrased as follows: Given the sparsity structure of a symmetric matrix A, obtain vectors $d_{1},d_{2},\ldots,d_{p}$ such that $Ad_{1},Ad_{2},\ldots,Ad_{p}$ determine A uniquely with p as small as possible. We approach this problem from a graph theoretic point of view and show that both direct and indirect approaches to this problem have a natural graph coloring interpretation. The complexity of the problem is analyzed and efficient practical heuristic procedures are developed. Numerical results illustrate the differences between the various approaches.

title: The Inherent Cost of Nonblocking Commitment
abstract: A commitment protocol orchestrates the execution of a distributed transaction, allowing each participant to "vote" on the transaction and then applying a pre-specified rule to decide the outcome (commit or abort). A nonblocking is able to correctly terminate a transaction at all operational participants in the presence of any number of benign processor failures. Herein, we derive strong lower bounds for both non-blocking protocols and their less fault-tolerant blocking counterparts. Results on message complexity are both surprising and encouraging: the message complexities of the two classes of protocols are identical. Results on time complexity were less encouraging: nonblocking protocols are approximately 50% more expensive.

However, we show how to overlap non-blocking executions of interfering transactions and thereby reduce their extra cost.

title: Some Linear-Time Algorithms for Systolic Arrays
abstract: We survey some recent results on linear-time and almost linear-time algorithms for one and two-dimensional systolic arrays. In particular, we show how the greatest common divisor (GCD) of two

polynomials of degree n over a finite field can be computed in time $O(n)$ on a linear systolic array of $O(n)$ cells; similarly for the GCD of two n-bit binary numbers. Assuming that the systolic cells can perform floating-point arithmetic, we show how n by n Toeplitz systems of linear equations can be solved in time $O(n)$ on a linear array of $O(n)$ cells, each of which has constant memory size (independent of n). Finally, we outline how a two-dimensional array of $O(n)$ by $O(n)$ cells with nearest-neighbor interconnections can be used to solve (to working accuracy) the eigenvalue problem for a symmetric real n by n matrix in time $O(nS(n))$. Here $S(n)$ is a slowly-growing function of n; for practical purposes $S(n)$ can be regarded as a constant. In addition to their theoretical interest, these results can be implemented relatively easily and have potential applications in the areas of error-correcting codes, symbolic and algebraic computation, signal processing and image processing. For example, systolic GCD arrays for error correction have been implemented with the microprogrammable "PSC" chip.

title: A Generalized Term Dependence Model in Information Retrieval
abstract: The tree dependence model has been used successfully to incorporate dependencies between certain term pairs on the information retrieval process, while the Bahadur Lazarsfeld Expansion (BLE) which specifies dependencies between all subsets of terms has been used to identify productive clusters of items in a clustered data base environment. The successes of these models are unlikely to be accidental; it is of interest therefore to examine the similarities between the two models. The disadvantage of the BLE model is the exponential number of terms appearings in the full expression, while a truncated BLE system may produce negative probability values. The disadvantage of the tree dependence model is the restriction to dependencies between certain term pairs only and the exclusion of higher-order dependencies. A generalized term dependence model is introduced in this study which does not carry the disadvantages of either the tree dependence or the BLE models. Sample evaluation results are included to demonstrate the usefulness of the generalized system.

title: Sparse Sets in NP-P: EXPTIME Versus NEXPTIME
abstract: This paper investigates the structural properties of sets in NP-P and shows that the computational difficulty of lower density sets in NP depends explicitly on the relations between higher deterministic and

nondeterministic time-bounded complexity classes. The paper exploits the recently discovered upward sparation method, which shows for example that there exist sparse sets in NP-P if and only if EXPTIME $\neq$ NEXPTIME. In addition, the paper uses relativization techniques to determine logical possibilities, limitations of these proof techniques, and, for the first time, to exhibit structural differences between relativized NP and CoNP.

title: Graph Coloring Using Eigenvalue Decomposition
abstract: Determining whether the vertices of a graph can be colored using k different colors so that no two adjacent vertices receive the same color is a well-known NP-complete problem. Graph coloring is also of practical interest (for example, in estimating sparse Jacobians and in scheduling), and many heuristic algorithms have been developed. We present a heuristic algorithm based on the eigenvalue decomposition of the adjacency matrix of a graph. Eigenvectors point out "bipartite-looking" subgraphs that are used to refine the coloring to a valid coloring. The algorithm optimally colors complete k-partite graphs and certain other classes of graphs with regular structure.

title: On the Optimum Checkpoint Selection Problem
abstract: We consider a model of computation consisting of a sequence of n tasks. In the absence of failures, each task i has a known completion time t_{i}. Checkpoints can be placed between any two consecutive tasks. At a checkpoint, the state of the computation is saved on a reliable storage medium. Establishing a checkpoint immediately before task i is known to cost s_{i}. This is the time spent in saving the state of the computation. When a failure is detected, the computation is restarted at the most recent checkpoint. Restarting the computation at checkpoint i requires restoring the state to the previously saved value. The time necessary for this action is given by r_{i}. We derive an $O(n^{3})$ algorithm to select out of the $n-i$ potential checkpoint locations those that result in the smallest expected time to complete all the tasks. An $O(n^{2})$ algorithm is described for the reasonable case where $s_{i} greater than s_{j}$ implies $r_{i} greater than r_{j}$. These algorithms are applied to two models of failure. In the first one, each task i has a given probability p_{i} of completing without a failure, i.e., in time t_{i}. Furthermore, failures occur independently and are detected at the end of the task during which they occur. The second model admits a continuous time failure mode where the failure intervals are independent and identically distributed random variables drawn from any given distribution. In this model, failures are detected immediately. In both models, the algorithm also gives the expected value of the overall completion time and we show how to derive all the other moments.

title: Merging Partitioned Databases
abstract: Partitioning of a distributed data base requires either that update activity be restricted or that a strategy for conflict resolution and partition merging be used once communication is restored. The graph-

theoretic approach used by Davidson follows the latter approach and can be used to show that finding an optimum solution to the general problem is NP-complete. We give several methods of reducing the size of the graphs involved. Two open subproblems are shown to be NP-complete, while an extension of a known polynomial-time subproblem is given. Simulation results are used to study both the amount of compression achieved by the graph reduction techniques and their effects on heuristics for the problem. In addition, some modifications are made to existing heuristics to improve their performance. A probabilistic model is presented and compared with the simulations.

title: Computation Times of NP Sets of Different Densities
abstract: In this paper, we study the computational complexity of sets of different densities in NP. We show that the deterministic computation time for sets in NP can depend on their density if and only if there is a collapse or partial collapse of the corresponding higher nondeterministic and deterministic time bonded complexity classes. We show also that for NP sets of different densities there exist complete sets of the corresponding density under polynomial time Turing reductions. Finally, we show that these results can be interpreted as results about the complexity of theorem proving and proof presentation in axiomatized mathematical systems. This interpretation relates fundamental questions about the complexity of our intellectual tools to basic structural problems about P, NP, CoNP, and PSPACE, discussed in this paper.

title: Partial Functions in Constructive Formal Theories
abstract: Partial functions abound in modern computing theory, and so any system which purports to naturally formalize it must treat them. Surprisingly, the most common treatments do not work well for constructive formal systems, i.e., for those with computational content. Since constructive formal systems are significant in computer science, it is important to give an account of partial functions in them. This paper does that by construing a partial function $\phi :N \rightarrow N$ as a total function $f:D_{f}\rightarrow N$ for D_{f} an inductively defined set generated simultaneously with f. This idea has appeared in other guises, at least in the author's previous work, but here it is presented in a pure form. It is compared to Scott's method of using total functions on domains. A formal system of arithmetic is defined to illustrate the ideas. The system is shown consistent relative to constructive type theory; from this result important corollaries are drawn about using the theory as a programming language. KEY WORDS AND PHRASES: automated logic, Heyting arithmetic, constructivity, intuitionistic predicate calculus, partial functions, recursive functions, programming logics, program verification, type theory, type checking.

title: The Nearly Ultimate Pearl
abstract: The PRL ("pearl") system is an environment providing computer assistance in the construction of formal proofs and programs in a particular formal theory, called the object theory. Certain proofs can in fact be considered as programs. The system embodies knowledge about programs in the form of rules of inference and in the form of facts stored in its library. Ultimately PRL may be regarded as an intelligent system for formal constructive problem solving in a large domain of mathematics. The PRL system is evolving in stages. Since our report "The Definition of Micro-PRL" in October 1981, we have had the experience of designing, building and using a complete core version of the system (called λPRL). We have also studied more deeply the theoretical issues raised in that report. We are now prepared to extend the core system closer to the "ultimate" PRL system envisioned earlier. This document describes the mathematical theory of types which is the object theory of that extension (called λPRL) and it is more or less self-contained. The type theory is defined in stages, starting from a constructive theory of integers and lists ("PRL). The development is a main feature of the paper.

title: Axiomatic Proof Techniques for Parallel Programs
abstract: This thesis presents an axiomatic method for proving certain correctness properties of parallel programs. Axioms and inference rules for partial correctness are given for two parallel programming languages: The General Parallel Language and the Restricted Parallel Language. The General Language is flexible enough to represent most standard synchronizers (e.g. semaphores, events), so that programs using these synchronizers may be verified using the GPL deductive system. However, proofs for GPL programs are in general quite complex. The Restricted Language reduces this complexity by requiring shared variables to be protected by critical sections, so that only one process at a time has access to them. This discipline does not significantly reduce the power of the language, and it greatly simplifies the process of program verification. Although the axioms and inference rules are primarily intended for proofs of partial correctness, there are a number of other important properties of parallel programs. We give some practical techniques which use information obtained from a partial correctness proof to derive other correctness properties, including program termination, mutual exclusion, and freedom from deadlock. A number of examples of such proofs are given. Finally, the axioms and inference rules are shown to be consistent and complete (in a special sense) with respect to an interpretive model of parallel execution. Thus the deductive system gives an accurate description of program execution and is powerful enough to yield a proof of any true partial

correctness formula.

title: Asynchronous Consensus and Byzantine Protocols in Faulty Environments
abstract: A consensus protocol enables a system of n aynchronous processes, some of which are faulty, to reach agreement. There are two kinds of faulty processes: fail-stop processes can only die, malicious processes can also send false messages. We investigate consensus protocols that terminate within finite time with probability 1 under certain assumptions on the behavior of the system. With fail-stop processes, we show that $\lceil (n + 1)/2 \rceil$ correct processes are necessary and sufficient to reach agreement. In the malicious case, we show that $\lceil (2n + 1)/3 \rceil$ correct processes are necessary and sufficient to reach agreement. This is contrasted with a recent result that there is no consensus protocol for the fail-stop case that always terminates within a bounded number of steps, even if only one process can fail. We also investigate the possibility of reliable broadcast (Byzantine Agreement) in an asynchronous system. We define the notion of Asynchronous Byzantine Agreement, and show that $\lceil (2n + 1)/3 \rceil$ correct processes are necessary and sufficient to reach Asynchronous Byzantine Agreement.

title: Some Considerations for Implementing the SMART Information Retrieval System Under UNIX
abstract: Since the early 1960's the SMART project has tested out new ideas in information science aimed at fully automatic document retrieval. Beginning in 1980 development of an enhanced and generalized version of SMART has progresses at Cornell. The current implementation is in the C language and runs under the UNIX operating system on a VAX 11/780 computer. The history of SMART is outlined. Considerations that led to the current design are described. Since SMART now allows multiple concept types to be manipulated in connection with an extended vector representation, storage and processing issues are discussed, including use of INGRES relations. Clustering algorithms are presented and run parameters are given for document clustering and subsequent clustered searching. SMART experiments (e.g. with p-norm queries, or probabilistic methods) can be compared using the evaluation package. The S statistical package can be applied to performing other special analysis and descriptive tasks. Finally, to illustrate the usefulness of these facilities, an outline is given of current SMART activities and of future plans.

title: Characterization of Two New Experimental Collections in Computer and Information Science Containing Textual and Bibliographic Concepts
abstract: Two new collections are described which are particularly useful for investigating the interaction

between textual and bibliographic data in the automatic indexing and retrieval of documents. An extension to the vector space model has been proposed whereby various types of concepts are included in the representation of such documents. Experiments using an enhanced version of the SMART system have shown such an extended model to perform better than simpler schemes. The CACM and ISI collections developed for this research should be of value for future related studies. The ISI collection has author, title/abstract, and co-citation data for the 1460 most highly cited articles and manuscripts in information science in the 1969-1977 period. The CACM collection contains 7 types of concepts for the 3204 articles published in the Communication of the ACM up through 1979. These collections have 76 and 52 queries, respectively, along with relevance judgments.

title: The Solution of Singular-Value and Symmetric Eigenvalue Problems on Multiprocessor Arrays
abstract: Parallel Jacobi-like algorithms are presented for computing a singular-value decomposition of an mxn matrix $(m \geq n)$ and an eigenvalue decomposition of an $n x n$ symmetric matrix. A linear array of $O(n)$ processors is proposed for the singular-value problem and the associated algorithm requires time $O(mnS)$, where S is the number of sweeps (typically $S \leq 10)$. A square array of $O(n^{2})$ processors with nearest-neighbor communication is proposed for the eigenvalue problem; the associated algorithm requires time $O(nS)$. Key Words And Phrases: Multiprocessor arrays, systolic arrays, singular-value decomposition, eigenvalue decomposition, real symmetric matrices, Hestenes method, Jacobi method, VLSI, real-time computation, parallel algorithms.

title: A Comparison of Two Methods for Boolean Query Relevance Feedback
abstract: The relevance feedback process uses information derived from an initially retrieved set of documents to improve subsequent search formulations and retrieval output. In a Boolean query environment this implies that new query terms must be identified and Boolean operators must be chosen automatically to connect the various query terms. In this study, two recently proposed automatic methods for relevance feedback of Boolean queries are evaluated and conclusions are drawn concerning the use of effective feedback methods in a Boolean query environment.

title: Mathematics as Programming
abstract: In a sufficiently rich programming language it is possible to express a very substantial amount of mathematics in a natural way. I don't mean only that one can write down functions or solve equations, I mean that one can write theorems and proofs. Moreover, expressing mathematics in this way reveals its computational content and makes it available for use with digital computers. This point is illustrated with reference to a programming language which is sufficiently rich in the above sense. I develop parts of Basic Recursive Function Theory and logic to illustrate the way in which doing some rather abstract mathematics is like programming. I chose BRFT in order to make certain points about the programming language by reflecting part of it inside itself. For example, while Church's Thesis can be false inside the language, it is true outside, reflecting in some sense the fact that while we may believe it, we do not expect to prove it. I chose a bit of logic to illustrate that the virtues of model theory (a certain abstractness and notation independence) are sometimes possible without sacrificing computational meaning.

title: On the Duality of Intersections and Closest Points
abstract: We call the common intersection of k objects a k-intersection. We address questions of the form: Given n objects in the plane, "Does there exist a k-intersection?", "How many such k-intersections exist?" and "What is the maximum value of k for which there exists a k-intersection?". In answering such questions we utilize a duality that exists between k-intersections and and k-closest points (the k points with the smallest enclosing circle), in that as long as k points are close enough to be enclosed by a circle of radius r, the common intersection of k circles of radius r centered at each of those k points (i.e. their k-intersection) is non-null. A technique, dubbed "rotation sorting" is then developed to provide efficient solutions to dual questions of the form: Given n points in the plane, "Does there exist a set of k points which can be covered by a circle of radius r?", "How many such sets of k points exist?", and "What are the maximum number of points that can be enclosed by a circle of radius r?". A similar duality between the intersection of a line with circles and the proximity of this line to the centers of the circles is exploited to obtain efficient algorithms for the transversals of circles in the plane. Extensions of the above questions to three and higher dimensions are also addressed, along with problems concerning unequal sized objects. Further certain generalizations of k-intersections and of the number of points enclosed by k objects in two dimensions and higher are shown to be NP-complete and D^{p}-complete.

title: Byzantine Generals In Action: Implementing Fail-Stop Processors
abstract: A fail-stop processor halts instead of performing an erroneous state transformation that might be visible to other processors, can detect whether another fail-stop processor has halted (due to a failure), and has a predefined portion of its storage that is unaffected by failures and accessible to any other fail-stop processor. Fail-stop processors can simplify construction of fault-tolerant computing systems. In this paper, the problem of approximating fail-stop processors is compared with the state machine approach, another general paradigm for constructing fault-tolerant systems.

title: Generalized Kolmogorov Complexity and the Structure of Feasible Computations
abstract: In this paper we define a generalized, two-parameter, Kolmogorov complexity of finite strings which measures how much and how fast a string can be compressed and we show that this string complexity measure is an efficient tool for the study of computational complexity. The advantage of this approach is that it not only classifies strings as random or not random, but measures the amount of randomness detectable in a given time. This permits the study how computations change the amount of randomness of finite

strings and thus establish a direct link between computational complexity and generalized Kolmogorov complexity of strings. This approach gives a new viewpoint for computational complexity theory, yields natural formulations of new problems and yields new results about the structure of feasible computations.

title: The Ultimate Planar Convex Hull Algorithm ?
abstract: We present a new planar convex hull algorithm with worst case time complexity $O(n \log H)$ where n is the size of the input set and H is the size of the output set, i.e. the number of vertices found to be on the hull. We also show that this algorithm is asymptotically worst case optimal on a rather realistic model of computation even if the complexity of the problem is measured in terms of input as well as output size. The algorithm relies on a variation of the divide-and-conquer paradigm which we call the "marriage-before-conquest" principle and which appears to be interesting in its own right.

title: Predicting Fill for Sparse Orthogonal Factorization
abstract: In solving large sparse linear least squares problems $Ax \cong b$, several different numeric methods involve computing the same upper triangular factor R of A. It is of interest to be able to compute the nonzero structure of R, given only the structure of A. The solution to this problem comes from the theory of matchings in bipartite graphs. The structure of A is modeled with a bipartite graph and it is

shown how the rows and columns of A can be rearranged into a structure from which the structure of its upper triangular factor can be correctly computed. Also, a new method for solving sparse least squares problems, called block back-substitution, is presented. This method assures that no unnecessary space is allocated for fill, and that no space is needed for intermediate fill.

title: Documentation for the CHIP Computer System (Version 1.1)
abstract: CHIP (Cornell Hypothetical Instructional Processor) is a computer system that was designed as an educational tool for teaching undergraduate courses in operating systems and machine architecture. This document constitutes the sole reference manual for the CHIP computer system. A simulator for this hypothetical system exists under the UNIX operating system. The CHIP architecture includes dynamic memory mapping suitable for implementing virtual memory, eight interrupt priority levels, memory-mapped input/output and two modes of processor operation. The central processor of CHIP is compatible with the PDP-11 at the user-mode instruction level. Therefore, any non-privileged code written for the PDP-11 can be

executed on CHIP. Several new user and kernel-mode instructions have been added to CHIP for increased efficiency. The CHIP simulator also supports input/output devices such as terminals, drums, disks and printers. All interactions with CHIP take place through an operator's console being simulated on a terminal. Users can examine/alter memory locations, set breakpoints, detect the referencing of specified memory locations, start/stop execution, etc. through a console command language. Program global variables and functions can be referred to by symbolic name with the mapping to absolute addresses being performed automatically by the system. The software support environment for CHIP includes a C compiler, assembler and loader.

title: Randomized Asynchronous Byzantine Agreements
abstract: A randomized protocol for reaching Byzantine Agreement in asynchronous systems with n processes was recently proposed in [Rabi83]. This protocol tolerates up to $\lfloor (n-1)/10 \rfloor$ faulty processes, and agreement is reached within an expected number of phases that is a small constant independent of n and the number of faulty processes t. In this paper, using the same computation model as in [Rabi83], it is shown that no Byzantine Agreement protocol can overcome more than $\lfloor (n-1)/3 \rfloor$ faulty processes in an asynchronous system, and we describe a protocol that achieves this upper bound. Agreement is also reached within an expected number of phases that is a small constant independent of n and t, but the communication complexity is higher than in [Rabi83}.

title: An Asynchronous [(n-1)/3]-Resilient Consensus Protocols
abstract: A consensus protocol enables a system of n asynchronous processes, some of them malicious, to reach agreement. No assumptions are made on the behaviour of the processes and the message system; both are capable of colluding to prevent the correct processes from reaching decision. A protocol is t-resilient if in the presence of up to t malicious processes it reaches agreement with probability 1. In a recent paper, t-resilient consensus protocols were presented for $t less than n / 5$. We improve this to $t less than n / 3$, thus matching the lower bound on the number of correct processes necessary for consensus. The protocol restricts the behaviour of the malicious processes to that of merely fail-stop processes, which makes it interesting in other contexts.

title: On One Tape Versus Two Stacks
abstract: We develop a simple method which enables us to prove three new lower bounds (for both worst and average cases) for on-line computations, answering two open problems summarized in [DGPR]. We give a language that requires $\Omega (n^{2})$ time for any 1-tape deterministic on-line machine, but it can be accepted by a 2-stack 1-reversal bounded deterministic on-line machine in real time. This provides a tight lower bound, closing the gap between $\Omega (n(logn)^{1/2})$ lower bound by [P2] and the trivial $O(n^{2})$ upper bound. We also prove that 1-tape nondeterministic real time is much stronger than its deterministic version. For 1-tape on-line machines, we give language L (L") which is in nondeterministic linear (real) time but requires $\Omega(n^{2})(\Omega (n^{1.5}))$ deterministic time. Finally we give a language which can be accepted by a 2-stack 1-reversal bounded deterministic machine in real time, but it requires $\Omega(n^{1+1/2})$ time for any one tape nondeterministic online machine. This sharply improves an $nlogn$ lower bound in [DGPR].

title: A Logic for the Russell Programming Language
abstract: We consider a programming language with a number of characteristics detrimental to conventional axiomatic descriptions. These include arbitrary side effects in expressions, aliasing among variables, very general recursive function declarations, and the ability to pass functions as parameters and return them as results. We give an axiomatic definition of this language based on a novel formalism. We prove the axiomatization sound and relatively complete with respect to a (somewhat nonstandard) denotational semantics. In spite of the nonstandard formalism, most conventional techniques for developing and reasoning about programs can be carried over. (ABRIDGED)

title: Implementing Fault-Tolerant Distributed Objects
abstract: This paper describes a technique for implementing k-resilient objects - distributed objects that remain available, and whose operations are guaranteed to progress to completion, despite up to k site failures. The implementation is derived from the object specification automatically, and does not require any information beyond what would be required for a non-resilient, non-distributed implementation. It is therefore unnecessary for an appplications programmer to have knowledge of the complex protocols normally employed to implement fault-tolerant objects. Our technique is used in ISIS, a system being developed at Cornell to support resilient objects.

title: Automatic Construction of CSP Programs from Sequential Non-Deterministic Programs
abstract: In this paper we describe a systematic method for transforming a sequential program, written in a guarded command language, into a distributed program, written in CSP. The variables of the sequential program are first partitioned into n disjoint sets, and then the program is transformed into a CSP program of n communicating processes. The two versions of the program are shown to be strongly equivalent, in the sense that they exhibit the properties of reaching the same final states and of either aborting, terminating, or running forever. We also discuss the conditions under which, when compared to the execution of the original sequential program, a speed-up in the execution of the resulting distributed program can be achieved.

title: The Sparse Null Space Basis Problem
abstract: The sparse null space basis problem is the following: $A t \times n$ matrix $A (t less than n)$ is given. Find a matrix N, with the fewest nonzero entries in it, whose columns span the null space of A. This problem arises in the design of practical algorithms for large-scale numerical optimization problems. Surprisingly, this problem can be formulated as a combinatorial optimization problem under a non-degeneracy assumption on A. THe theory of matchings in bipartite graphs - marriage theorems - can then be used to obtain the nonzero positions in N. Numerically stable matrix factorizations are used in the next phase to compute N. We use conformal decompositions to characterize the columns of a sparsest null basis. Matroid theory is used to prove that a greedy algorithm constructs a sparsest null basis. We prove that finding a sparsest null basis is NP-hard by showing that associated matroidal and graph-theoretic problems are NP-complete. We propose two approximation algorithms to construct sparse null bases. Both of them make use of the Dulmage-Mendelsohn decomposition of rectangular matrices. One algorithm is a sparsity exploiting variant of the variable-reduction technique. The second is a locally greedy algorithm that constructs a null basis with an upper triangular submatrix. These results are extended to computing sparse orthogonal null bases. We discuss how this "two-phase" approach can construct sparser null bases than a purely numerical approach; it is also potentially faster than the latter. Finally, we classify all known methods for constructing null bases, and show some unexpected equivalences between some of them.

title: Buffer Management as Inventory Control
abstract: We consider computer subsystems that use buffering as a mechanism to enhance communication performance between two or more components exhibiting a short-term speed mismatch. Often, a fixed size buffer is inserted in such a communication path since it can improve performance by dampening speed variations. We formalize this buffer management problem within the framework of inventory control theory. We show that among all admissible policies for controlling such communications, the structure of the optimal one is analogous to the reorder point/order up to level policy that arises in the single commodity, continuous review, inventory control problem. This confirms the appropriateness of the intuitive and often-used high water mark/low water mark policy for buffer management. Given this policy structure, we derive expressions for the optimal parameter values. We discuss extensions of these results whereby policy parameters are dynamically estimated based on current observations of the communication characteristics. An algorithm to generate the optimal ordering decisions (and resulting costs) when communication patterns are known a priori is developed as a useful benchmark for evaluating the goodness of on-line policies.

title: A Taxonomy of Parallel Sorting
abstract: In this paper, we propose a taxonomy of parallel sorting that includes a broad range of array and file sorting algorithms. We analyze the evolution of research on parallel sorting, from the earliest sorting networks to the shared memory algorithms and the VLSI sorters. In the context of sorting networks, we describe two fundamental parallel merging schemes - the odd-even and the bitonic merge. Sorting algorithms have been derived from these merging algorithms for parallel computers where processors communicate through interconnection networks such as the perfect shuffle, the mesh and a number of other sparse networks. After describing the network sorting algorithms, we show that, with a shared memory model of parallel computation, faster algorithms have been derived from parallel enumeration sorting schemes, where keys are first ranked and then rearranged according to their rank. Parallel sorting algorithms are evaluated according to a number of criteria, related not only to their time complexity, but also to their feasibility from a computer architecture point of view. We show that in addition to their attractive communication schemes, network sorting algorithms have non-adaptive schedules that make them suitable for implementation. In particular, they are easily generalized to block-sorting algorithms, that utilize limited parallelism to solve large sorting problems. We also address the problem of sorting large mass-storage files in parallel, using modified disk devices or intelligent bubble memories. Finally, the newer area of VLSI sorting is mentioned as an active and promising direction of research on parallel sorting.

title: On the Motion of Objects in Contact
abstract: There is an increasing use of computers in the design, manufacture and manipulation of physical objects. An important aspect of reasoning about such actions concerns the motion of objects in contact. The study of problems of this nature requires not only the ability to represent physical objects but the development

of a framework or theory in which to reason about them. In this paper such a development is investigated and a fundamental theorem concerning the motion of objects in contact is proved. The simplest form of this theorem states that if two objects in contact can be moved to another configuration in which they are in contact, then there is a way to move them from the first configuration to the second configuration such that the objects remain in contact throughout the motion. This result is proved when translation and rotation of objects are allowed. The problem dealing with more generalized types of motion is also discussed. This study has obvious applications in compliant motion and in motion planning.

title: Independence Results about Context-Free Languages and Lower Bounds
abstract: We show that for any axiomatizable, sound formal system F there exist instances of natural problems about context-free languages, lower bounds of computations and P versus NP that are not provable in F for any recursive representqation of these problems. Most previous independence results in computer science have been proven for specific representations of the problems, by exploiting the "opaqueness" of Turing machine names. Our results rely on the complexity of the logical structure of the problem and yield independence results which do not depend on the representations of problems. We show, for example, that there exists a non-regular context-free language L_{o} such that for no cf-grammar $G, L(G) = L_{o}$, it

is provable in F that "L(G) is not regular". We also show, among other results P and NP, that there exists a recursive oracle A such that $NP^{A} \neq P^{A}$, and that this fact is not provable in F for any recursive representation of A. The difference of what is and is not provable in F is well illustrated by questions about polynomial time isomorphisms (p-isomorphisms) of NP complete sets. We show that for every NP complete set, L, there is a representation of L by a non-deterministic polynomial time machine for which we can prove that L is NP complete. Furthermore if L is p-isomorphic to SAT then this is also provable in F for some representation of L. On the other hand, if there exist NP complete sets not p-isomorphic to SAT then there exists an NP complete set L for which, independent of its representation, there is no proof in F that L is or is not p-isomorphic to SAT.

title: Reducibility among Geometric Location-Allocation Optimization Problems
abstract: Three different classes of multiple points location-allocation problems in the Euclidean plane are considered under a discrete optimization criterion which minimizes the maximum cost based on certain interpoint distances. Each of these classes of geometric optimization problems is studied with three different distance metrics (Euclidean, Rectilinear, Infinity) as well as for feasible solution sets in the plane which are both discrete and infinite. All of these problems are shown to be polynomial-time reducible to each other and furthermore D^{p} complete.

title: Automatic Assignment of Soft Boolean Operators
abstract: The conventional bibliographic retrieval systems are based on Boolean query formulations and inverted file implementations. Such systems provide rapid responses in answer to search queries but they are not easy to use by uninitiated patrons. An extended Boolean retrieval strategy has been devised in which the Boolean operators are treated more or less strictly, depending on the setting of a special parameter, known as the p-value. The extended system is much more forgiving than the conventional system, and provides better retrieval effectiveness. In this study various problems associated with the determination of appropriate p-values are discussed, and suggestions are made for an automatic assignment of p-values. Evaluation output is included to illustrate the operations of the suggested procedures.

title: Distributed Agreement in the Presence of Processor and Communication Faults
abstract: A model of distributed computation is proposed in which processes may fail by not sending or receiving the messages specified by a protocol. The solution to the Byzantine Generals Problem for this model is presented. Our algorithm exhibits early-stopping under conditions of less than maximum failure and is as efficient as the algorithms developed for the more restrictive crash-fault model in terms of time, message, and bit complexity. We show extant models to under-estimate resiliency when faults in the communication medium are considered; the model of this paper is more accurate in this regard.

title: Patterns of Communication in Consensus Protocols
abstract: This paper presents a taxonomy of consensus problems, based on their safeness and liveness properties, and then explores the relationships among the different problems in the taxonomy. Each problem is characterized by the communication patterns of protocols solving it. This then becomes the basis for a new notion of reducibility between problems. Formally, problem P_{1} reduces to problem P_{2} whenever each set of communication patterns of a protocol for P_{2} is the set of comunication patterns of a protocol for P_{1}. This means intuitively that any protocol for P_{2} can solve P_{1} by relabeling local states and padding messages. Consequently, the message complexity (measured in number of messages) of P_{1} is not greater than the message complexity of P_{2}. Our method of characterizing and comparing problems is the principal contribution of this paper.

title: Computing the CS and the Generalized Singular Value Decompositions
abstract: If the columns of a matrix are orthonormal and it is partitioned into a 2-by-1 block matrix, then the singular value decompositions of the blocks are related. This is the essence of the "CS decomposition". The computation of these related SVD's requires some care. Stewart has given an algorithm that uses the LIN-PACK SVD algorithm together with a Jacobi-type "clean-up" operation on a cross-product matrix. Our technique is equally stable and fast but avoids the cross-product matrix. The simplicity of our technique makes it more amenable to parallel computation on systolic-type computer architectures. These developments are of interest because the best way to compute the generalized singular value decomposition of a matrix pair (A,B) is to compute the CS decomposition of a certain orthogonal column matrix related to A and B.

title: Thrifty Execution of Task Pipelines
abstract: A sequence of tasks that must be performed on a sequential database can be scheduled in various ways. Schedules will differ with respect to the number of accesses made to peripheral storage devices and the amount of memory space consumed by buffers. Buffer requirements are discussed for task schedules that avoid accesses to peripherals storing the sequential database. The relationship between certain thrifty scheduling policies and loop jamming, a standard code optimization technique, is also identified. Application to UNIX pipelines and to file processing is discussed.

title: Reducing Multiple Object Motion Planning To Graph Searching
abstract: In this paper we study the motion planning problem for multiple objects where an object is a 2-dimensional body whose faces are line segments parallel to the axes of R^{2} and translations are the only motions allowed. Towards this end we analyze the structure of configuration space, the space of points that correspond to positions of the objects. In particular, we consider CONNECTED, the set of all points in configuration space that correspond to configurations of the objects where the objects form one connected component. We show that CONNECTED consists of faces of various dimensions such that if there is a path in CONNECTED between two 0-dimensional faces (vertices) of CONNECTED then there is a path between them along 1-dimensional faces (edges) of CONNECTED. It is known that if there is a motion between the configurations. Thus by the result of this paper the existence of a motion between two vertices of CONNECTED implies a motion corresponding to a path along edges of CONNECTED. Hence we have reduced the motion planning problem from a search of a high dimensional space to a graph searching problem. Searching the graph of vertices and edges of CONNECTED for a path has a prohibitive worse-case complexity because of the large number of vertices and edges. However, if the search generates edges and vertices only as they are needed, a practical and efficient algorithm may be possible using some effective heuristic. From this result it is shown that motion planning for rectangles in a rectangular boundary is in PSPACE. Since it is known that the problem is PSPACE-hard we conclude it is a PSPACE-complete problem.

title: Algebraic Specification of a Communication Scheduler
abstract: A distributed programming language normally incorporates one mechanism by which processes communicate with each other. This mechanism can be used to transfer information or to synchronize the flow of control in the program. Different communication mechanisms have been proposed for different languages. In this paper, we provide a common framework in which these mechanisms can be examined independently of the languages in which they may be embedded. Operationally, this framework is a communication scheduler: formally, it is specified algebraically as a data type. A number of different communication mechanisms, such as synchronous and asynchronous message passing, broadcasts and remote procedure calls, are modelled and, as an illustration of how global properties can be analysed, we consider the problem of deadlock detection.

title: Disambiguation, Correctness and Flow-Analysis Issues for Trace Scheduling Compilers
abstract: Trace scheduling is a global compaction technique for transforming sequential programs into parallel code. When this investigation began, trace scheduling was unimplemented and many serious questions of appropriateness and effectiveness needed to be solved. This paper addresses questions of its applicability to ordinary programming for Very Long Instruction Word machines. We developed practical methods of exploiting this parallelism (e.g. memory anti-aliasing). To justify and better understand the dynamic interaction between trace scheduling and anti-aliasing, we designed a more formal model in which we proved the correctness of trace scheduling and showed that it terminates. This in turn allowed us to analyze our flow information requirements. Finally we addressed the problem of ambiguous memory references which cannot be resolved at compile time.

title: Intersection Graph Algorithms
abstract: An intersection graph for a set of sets C is a graph G together with a bijection from the vertices of G to C such that distinct vertices in G are adjacent if and only if their images under this bijection intersect. Of particular interest have been the classes of chordal graphs, the intersection graphs of sets of subtrees of a tree, and interval graphs, the intersection graphs of sets of intervals of the real line. I examine another class of intersection graphs, the class of directed path graphs: intersection graphs of sets of paths in a directed tree. This class properly contains the class of interval graphs, and is properly contained by the class of chordal graphs. I give a linear time algorithm for recognizing directed path graphs and for constructing intersection representations, and a polynomial time algorithm for deciding directed path graph isomorphism. Both algorithms use a data structure called a partial path tree, which is a kind of skeletal representation of the clique hypergraph of a directed path graph. I present linear time algorithms for finding partial path trees with specific roots and for finding partial path trees with arbitrary roots. I prove that partial path trees with identical roots are identical. Using this fact I develop a polynomial time algorithm for directed path graph isomorphism.

title: Geometric Optimization and Computational Complexity
abstract: Our purpose here is to study problems involving geometric optimization, namely, questions of the type: Is there at least a minimum or at most a maximum number of certain geometric figures, that are within certain distances of other figures (objects). We are also concerned with the optimization of the size of these geometric figures. These problems arise as geometric reductions from various classes of location-allocation optimization problems and are inherently not pure combinatorial. Our primary aim, then, is to discover techniques of dealing with such geometric optimization problems, while adapting to these problems the older combinatorial design and analysis methods. The task of classifying problems accurately in the polynomial hierarchy is one of increasing importance. To solve an optimization problem deterministically it seems that one must solve both an NP and a $Co-NP$ problem. The significance of the classes NP and $Co-NP$ are that none of the problems they include is known to have a polynomial time solution. We show that if $NP \neq Co-NP$ then there are interesting natural geometric optimization problems (location-allocation problems under minsum) in Δ^{P}_{2} that are in neither NP nor $Co-NP$. Hence, all these problems are shown to belong properly to Δ^{P}_{2}, the second level of

the polynomial hierarchy. We also show that if $NP \neq Co-NP$ then there are again some interesting geometric optimization problems (location-allocation problems under minmaz) properly in Δ^{P}_{2} and furthermore they are complete for a class D^{P} (which is contained in Δ^{P}_{2} and contains $NP \bigcup Co-NP$). Also considered are the above geometric location-allocation optimization problems for the case when the allocation is predetermined. Both efficient algorithms and worst-case lower bounds are derived. Necessary conditions for the existence of mazima and minima in optimization problems are generally tied to the question of solvability of an equation or a system of equations. In calculus these equations are algebraic. By generating the minimal polynomial whose root over the field of rational numbers is the solution of the geometric optimization problem on the real (Euclidean) plane, we are able to prove the non-solvability of certain geometric optimization problems by radicals. The algebraic degree of the optimizing solution, which is the degree of the irreducible minimal polynomial for the problem, correlates with the inherent difficulty of constructing the solution and provides an algebraic complexity measure for these geometric optimization problems.

title: Formal Model of MOS Clocking Disciples
abstract: This paper presents a formalization of clocking disciplines used to prevent race conditions in VLSI circuits. A signal-labeling scheme for the two-phase clocking discipline informally described in Mead and Conway [MC] is presented. Rules are given for checking the correct labeling of a circuit consisting of combinatorial logic and memory elements. The signal-labeling conventions are based in part on those of

Noice, Mathews, and Newkirk [NMN]. A formal basis is presented for constructing signal-labeling schemes for multi-phase clocks (both overlapping and non-overlapping) from a definition of the master timing signals. The two-phase scheme is shown to be a special case of this general method. The method is also illustrated for four-phase overlapping clocks.

title: Lower Bounds on String-Matching
abstract: New techniques for obtaining lower bounds on string-matching problems are developed and we prove the following new results. String-matching cannot be performed by a three-head one-way deterministic finite automaton. This answers the $k=3$ case of the open question, due to Galil and Seiferas [GS], whether a k-head one-way deterministic finite automaton can perform string-matching. String-matching by a k-head two-way DFA with k-1 heads blind (can only see two end symbols) is studied, tight upper and lower bounds are provided. Probabilistically moving a string on one tape (requiring n^{2} time) is harder than probabilistically matching two strings on 1 tape. Notice that this is not true for deterministic or even nondeterministic TMs. This is the first result showing that checking is easier than generating.

title: Finding Minimal Perfect Hash Functions

abstract: A heuristic is given for finding minimal perfect hash functions without extensive searching. The procedure is to construct a set of graph (or hypergraph) models for the dictionary, then choose one of the models for use in constructing the minimal perfect hashing function. The construction of this function relies on a backtracking algorithm for numbering the vertices of the graph. Careful selection of the graph model limits the time spent searching. Good results have been obtained for dictionaries of up to 181 words. Using the same techniques, non-minimal perfect hash functions have been found for sets of up to 667 words.

title: Derivation of a Maximally Parallel Algorithm for Balancing Binary Search Trees
abstract: A recent trend in program methodologies is to derive efficient parallel programs from sequential programs. This paper explores the question of transforming a sequential algorithm into an efficient parallel algorithm by considering the problem of balancing binary search trees. The derivation of the parallel algorithm makes use of stepwise refinement. We first derive a new iterative balancing algorithm that exploits the similarity of pointer restructuring required at all the nodes at the same level. From this we derive a parallel algorithm that has time complexity O(1) on an N-processor configuration. This achieves the theoretical limit of speed-up possible in a multi-processor configuration.

title: Universally Closed Classes of Total Computable Functions
abstract: One of the most important characteristics of universal programming languages is that they can express their own semantics, that is universal partial functions, say interpreters, can be defined in the language. A fundamental result of computability theory is that no class of total functions can contain its own universal function. In practical terms this is disappointing, one must give up the advantages of universality to gain those of totality. In this paper the fundamental negative result is circumvented for programming languages with a sufficiently rich type structure. A new method is given for building a universally closed class of total computable functions starting with any class of such functions. These results have direct practical application in programming logics, and they raise new questions for computability theory.

title: General Correctness: A Unification of Partial and Total Correctness
abstract: General correctness, which subsumes partial and total correctness, is defined for both weakest preconditions and strongest postconditions. Healthiness properties for general-correctness predicate

transformers are more uniform and complete than those for partial-and-total-correctness systems. In fact, the healthiness properties for partial and total correctness are simple restrictions of those for general correctness. General correctness allows simple formulations of the connections between weakest and strongest postconditions and between the notions of weakest precondition under the "demonic" and "angelic" interpretations of nondeterminism. A problem that plagues $sp - sp(P, C)$ is undefined if execution of C begun in some state of P may not terminate - disappears with the generalization. This paper is a study of some simple theory underlying predicate transformer semantics, and as yet has little bearing on current programming practices. The theory uses a relational model of programs.

title: An Overview of the Isis Project
abstract: The goal of the ISIS projest is to provide a high-level support for fault-tolerant distributed computing by automatically replicating data and code. The extent to which information is replicated and the physical location of information are not specified directly by the programmer, but are instead inferred from a specification, which looks much like a conventional program in an object-oriented language. This novel approach to fault-tolerant software construction requires much less sophistication from programmers than current alternatives. Moreover, optimization techniques that would be too complex for implementation in general purpose applications can be supported by the ISIS system. This overview discusses the goals of the project, its current status, and some of the implications of our work.

title: Proof Rules for Fault-Tolerant Distributed Programs
abstract: Proving properties of fault tolerant distributed programs is a complex task as such proofs must take into account failures at all possible points in the execution of individual processes. The difficulty in accomplishing this is compounded by the need also to cater for simultaneous failures of two or more processes. In this paper, we consider programs written in a version of Hoare's CSP and define a set of axioms and inference rules by which proofs can be constructed in three steps: proving the properties of each process when its communicants are prone to failure, establishing the effects of failure of each process, and combining these proofs to determine the fault tolerant properties of the whole program.

title: Low Cost Management of Replicated Data in Fault-Tolerant Distributed Systems
abstract: Many distributed systems replicate data for fault tolerance or availability. In such systems, a logical update on a data item results in a physical update on a number of copies. The synchronization and communication required to ensure that the copies of replicated data are kept consistent introduces a delay when operations are performed. In this paper, we describe a technique that relaxes the usual degree of synchronization, permitting copies of replicated data to be updated concurrently with other operations, while at the same time ensuring that correctness is not violated. The additional concurrency thus obtained results in better response time when performing operations on replicated data. We also discuss how this

technique performs in conjunction with roll-back and roll-forward failure recovery mechanisms.

title: The Cyclic Coloring Problem and Estimation of Sparse Hessian Matrices
abstract: Numerical optimization algorithms often require the (symmetric) matrix of second derivatives, $\nabla^{2} f (x)$, of some problem function $f: R^{n} \rightarrow R^{1}$. If the Hessian matrix is large and sparse then estimation by finite differences can be quite attractive since several schemes allow for estimation in $\ll n$ gradient evaluations. The purpose of this paper is to analyze, from a combinatorial point of view, a class of methods known as substitution methods. We present a concise characterization of such methods in graph-theoretic terms. Using this characterization, we develop a complexity analysis of the general problem and derive a roundoff error bound on the Hessian approximation. Moreover, the graph model immediately reveals procedures to effect the substitution process optimally (ie. using fewest possible substitutions given the differencing directions) in space proportional to the number of nonzeroes in the Hessian matrix.

title: Signal Processing Computations Using the Genralized Singular Value Decomposition
abstract: The ordinary Singular Value Decomposition (SVD) is widely used in statistical and signal processing

computation, both for the insight it provides into the structure of a linear operator, and as a technique for reducing the computational word length required for least-squares solutions and certain Hermitian eigensystem decompositions by roughly a factor of two, via computing directly on a data matrix, rather than on the corresponding estimated correlation or covariance matrix. Although the SVD has long been utilized as a method of off-line or non-real-time computation, parallel computing architectures for its implementation in near real time have begun to emerge. The Generalized Singular Value Decomposition (GSVD) bears the same relationship to the computation of certain Hermitian generalized eigensystem decompositions that the ordinary SVD bears to the corresponding ordinary eigensystem decompositions. This paper discusses methods for computing the GSVD via a sequence of more familiar computations and indicates the relation of the GSVD to the MUSIC algorithm of R. Schmidt.

title: How Near is a Stable Matrix to an Unstable Matrix?
abstract: In this paper we explore how close a given stable matrix A is to being unstable. As a measure of "how stable" a stable matrix is, the spectral abscissa is shown to be flawed. A better measure of stability is the Frobenius norm of the smallest perturbation that shifts one of A's eigenvalues to the imaginary axis. This leads to a singular value minimization problem that can be approximately solved by heuristic means. However, the minimum destabilizing perturbation may be complex even when A is real. This suggests that in the real case we look for the smallest real perturbation that shifts one of the eigenvalues to the imaginary axis. Unfortunately, a difficult constrained minimization problem ensues and no practical estimation technique could be devised.

title: A Model and Temporal Proof System for Networks of Processes
abstract: A model and a sound and complete proof system for networks of processes in which component processes communicate exclusively through messages is given. The model, an extension of the trace model, can desribe both synchronous and asynchronous networks. The proof system uses temporal-logic assertions on sequences of observations - a generalization of traces. The use of observations (traces) makes the proof system simple, compositional and modular, since internal details can be hidden. The expressive power of temporal logic makes it possible to prove temporal properties (safety, liveness, precedence, etc.) in the system. The proof system is language-independent and works for both synchronous and asynchronous networks.

title: Resilient Communication Structures for Local Area Networks
abstract: Reliable communication is crucial to the correct functioning of distributed systems. We propose a multi-ring communication structure and a reconfiguration algorithm that tolerate multiple link failures before the network divides into more than one partition. In case of partitioning, each partition is reconfigured to allow communication among the sites within the partition. The algorithm handles recovery of links and merges partitions once links become operational again. The algorithm itself is fault-tolerant, and it is fully

distributed and does not require global knowledge about the status of the network at any one site.

title: An Approach to the Functional Description of an Information Retrieval System Based on a Generalized Model
abstract: In this paper, the authors present a high level, functional approach to the description of a generalized information retrieval system. The description is based on the top-down decomposition of the system into modules and processes and on an appropriate data abstraction. The purpose of this paper is to describe the behavior of the system in terms of the component processes and the interactions of these processes in terms of inputs, outputs, and the associated transformations. It allows one to view the system as a collection of abstract processes, each of which is concisely defined via a notation that describes what is accomplished but not how such a process is to be implemented. Semantically irrelevant details are removed, thereby producing a nonprocedural description which not only elucidates system behavior but serves as a basis for subsequent formal specification.

title: Streets of Byzantium: Network Architecture for Fast Reliable Broadcasts
abstract: A site broadcasting its local value to all other sites in a fault-prone environment is a fundamental paradigm in constructing reliable distributed systems. Time complexity lower bounds and network connectivity requirements for reliable broadcast protocols in point-to-point communication networks are

well known. In this paper we consider the reliable broadcast problem in distributed systems with broadcast networks (for example, Ethernets) as the basic communication architecture. We show how properties of such network architectures can be used to effectively restrict the externally visible behavior of faulty processors. We use these techniques to derive simple protocols that implement reliable broadcast in only two rounds, independent of the failure upper bounds.

title: State Machines and Assertions (An Integrated Approach to Modelingand Verification of Distributed Systems
abstract: This paper describes a methodology for modeling and verifying protocols for asynchronous message passing systems. It combines the techniques of finite state analysis and axiomatic verification. It overcomes the problem of state explosion by using variables and logical assertions where the finite state approach would require a large number of states. By explicitly including states where interactions between processes occur, the complexity of assertional proofs is significantly reduced. Properties like freedom from deadlock, freedom from unspecified message receptions, boundedness of channel size, and partial correctness can be proved. Properties of channels like losing or garbling messages can be modeled, as can premature and non-premature timeouts. The technique is illustrated by proving a sliding window flow control protocol and an alternating bit protocol that is correct only if timeouts are non-premature.

title: The Cluster Hypothesis Revisited
abstract: A new means of evaluating the cluster hypothesis is introduced and the results of such an evaluation are presented for four collections. The results of retrieval experiments comparing a sequential search, a cluster-based search, and a search of the clustered collection in which individual documents are scored against the query are also presented. These results indicate that while the absolute performance of a search

on a particular collection is dependent on the pairwise similarity of the relevant documents, the relative effectiveness of clustered retrieval versus sequential retrieval is independent of this factor. However, retrieval of entire clusters in response to a query usually results in a poorer performance than retrieval of individual documents from clusters.

title: Recursive Definitions in Type Theory
abstract: The type theories we consider are adequate for the foundations of mathematics and computer science. Recursive type definitions are important practical ways to organize data, and they express powerful axioms about the termination of procedures. In the theory examined here, the demands of practicality arising from our implemented system, Nuprl, suggest an approach to recursive types that significantly increases the proof theoretic power of the theory and leads to insights into computational semantics. We offer a new account of recursive definitions for both types and partial functions. The computational requirements of the theory restrict recursive type definitions involving the total function-space constructor ($\rightarrow$) to those with only positive occurrences of the defined type. But we show that arbitrary recursive definitions with respect to the partial function-space constructor are sensible. The partial function-space constructor allows us to express reflexive types of Scott's domain theory (as needed to model the lambda calculus) and thereby reconcile parts of domain theory with constructive type theory.

title: Lower Bounds by Kolmogorov-Complexity
abstract: Using Kolmogorov-complexity, we obtain the following new lower bounds. For on-line nondeterministic Turing machines, (1) simulating 2 pushdown stores by 1 tape requires $\Omega(n^{1.5} / logn)$ time; together with a newly proved $O(n^{1.5}\sqrt{logn})$ upper bound [L3], this basically settled the open problem 1 in [DGPR] for 1 tape vs. 2 pushdown case (the case of 1 tape vs. 2 tapes was basically settled by [M]); (2) simulating 1 queue by 1 tape requires $\Omega(n^{4/3} / logn)$ time; this brings us closer to a newly proved $O(n^{1.5}\sqrt{logn})$ upper bound [L3]; (3) simulating 2 tapes by 1 tape requires $\Omega(n^{2} / lognloglogn)$ time; this is a minor improvement of [M]'s $\Omega(n^{2} / log^{2}nloglogn)$ lower bound; it is also claimed (full proof contained in [L3]) that the actual languages used in [M] (also here) and [F] do not yield $\Omega(n^{2})$ lower bound. To cope with an open question of [GS] of whether a k-head 1-way DFA (k-DFA) can do string matching, we develop a set of techniques and show that 3-DFA cannot do string matching, settling the case $k = 3$. Some other related lower bounds are also presented.

title: Simulating Two Pushdown Stores by One Tape in $O(n^{1.5}\sqrt{logn}$) Time. (Preliminary Version)

abstract: Based on two graph separator theorems, one old (the Lipton-Tarjan planar separator theorem) and one new, we present two unexpected upper bounds and resolve several open problems for on-line computations: (1) 1 tape nondeterministic machines can simulate 2 pushdown stores in time $O(n^{1.5} \sqrt{logn})$ (true for both on-line and off-line machines). Together with the $\Omega (n^{1.5} \sqrt{logn})$ lower bound by the author [L1], this solved the open problem 1 in [DGPR] for the 1 tape vs. 2 pushdown case. It also disproves the commonly conjectured $\Omega (n^{2})$ lower bound. (Note, the $\Omega (n^{2})$ lower bound has been proved for the deterministic case [M, L, V].) (2) the languages defined by [M] and [F], aimed to obtain optimal lower bound for 1 tape nondeterministic machines, can be accepted in $O(n^{2} loglogn / \sqrt{logn})$ and $O(n^{1.5}\sqrt{logn})$ time by a 1 tape TM, respectively. (3) 3 pushdown stores are better than 2 pushdown stores. This answers open problem 3 of [DG]. (An $\Omega(n^{4/3} / log^{e} n)$ lower bound is also obtained.) (4) 1 tape can nondeterministically simulate 1 queue in $O(n^{1.5} \sqrt{logn})$ time. (The lower bounds were: $\Omega(n^{2})$ for deterministic case [V] and $\Omega(n^{4/3} / logn)$ [L1] for nondeterministic case.)

title: Replication and Fault-Tolerance in the ISIS System
abstract: The ISIS system transforms abstract type specifications into fault-tolerant distributed implementations while insulating users from the mechanisms used to achieve fault-tolerance. This paper discusses techniques for obtaining a fault-tolerant implementation from a non-distributed specification and for achieving improved performance by concurrently updating replicated data. The system itself is based on a small set of communication primitives, which are interesting because they achieve high levels of concurrency while respecting higher level ordering requirements. The performance of distributed fault-tolerant services running on this initial version of ISIS is found to be nearly as good as that of non-distributed, fault-intolerant ones.

title: Voronoi Diagrams and Arrangements
abstract: We propose a uniform and general framework for defining and dealing with Voronoi Diagrams. In this framework a Voronoi Diagram is a partition of a domain D induced by a finite number of real valued functions on D. Valuable insight can be gained when one considers how these real valued functions partition $D \times R$. With this view it turns out that the standard Euclidean Voronoi Diagram of point sets in R^{d} along with its order-k generalizations are intimately related to certain arrangements of hyperplanes. This fact can be used to obtain new Voronoi Diagram algorithms. We also discuss how the formalism of arrangements can be used to solve certain intersection and union problems.

title: On Complete Problems for NP$\cap$CoNP
abstract: It is not known whether complete languages exist for $NP\cap CoNP$, and Sipser has shown that there are relativizations so that $NP\cap CoNP$ has no $\leq ^{P}_{m}$-complete languages. In this paper we show that $NP\cap CoNP$ has $\leq ^{P}_{m}$-complete languages if and only if it has $\leq ^{P}_{T}$-

complete languages. Furthermore, we show that if a complete language L_{0} exists for $NP\cap CoNP$ and $NP\cap CoNP \neq NP$ then the reduction of $L(N_{i}) \in NP\cap CoNP$ cannot be effectively computed from N_{i}. We extend the relativization results by exhibiting an oracle E such that $P^{E} \neq NP^{E} \cap CoNP^{E} \neq NP^{E}$ and for which there exist complete languages in the intersection. For this oracle the reduction to a complete language can be effectively computed from complementary pairs of machines (N_{i}, N_{j}) such that $L(N_{i})= \overline{L(N_{j})}$. On the other hand, there also exist oracles F such that $P^{F} \neq NP^{F} \cap CoNP^{F} \neq NP^{F}$ for which the intersection has complete languages, but the reductions to the complete language cannot be effectively computable from the complementary pairs of machines. In this case, the reductions can be computed from $(N_{i}, N_{j}$, Proof that $L(N_{i})= \overline{L(N_{j})}).$

title: A Better Tool for Query Optimization
abstract: When evaluating the performance of a query strategy, one must often estimate the number of distinct values of an attribute in a randomly selected subset of a relation. Most query optimizers compute this estimate based on the assumption that prior to the selection, the attribute values are uniformly distributed in the relation. In this paper we depart from this assumption and instead consider Zipf distributions that are known to accurately model text and name distributions. Given a relation of cardinality n where a non-key attribute A has a Zipf distribution, we derive both an exact formula and an approximate non-iterative formula for the expected number of distinct A-values contained in a sample of k randomly selected tuples. The approximation is accurate, and it is very easy to compute. Thus it provides a practical tool to deal with non-uniform distributions in query optimization.

title: The Homogenous Capture of Random Strings
abstract: It is well known that a set of strings that are random in the Kolmogorov sense is immune to all computable enumerations. In this paper, we discuss the generalization of this property to the computational resource hierarchies. We then introduce the notion of homogeneous capture of sets and show that sets of random strings are not homogeneously captured by any computable enumeration. Again, we discuss the extension of this property to the resource hierarchies. Finally, we discuss the relationship between the notion of homogeneous capture and the traditional concept of randomness.

title: Wide Quotient Trees for Finite Element Problems
abstract: In solving the system of linear equations $Ax = b$ where A is an $n \times n$ large sparse symmetric positive definite matrix, one important objective is to minimize fill. One approach is to partition the matrix so that its corresponding quotient graph is a tree and then use block factorization techniques to solve the system. We examine several methods for generating valid quotient tree partitionings of grid graphs and find that those producing short wide quotient trees are superior for large enough graphs. We then give

an algorithm for generating wide quotient tree partitionings of a more general class of graphs. Bounds on its storage and computational requirements are provided and compared to those of a generalized nested dissection algorithm.

title: Percolation Scheduling: A Parallel Compilation Technique
abstract: Percolation Scheduling (PS) is a new technique for compiling programs into parallel code. It attempts to overcome problems that limit the effectiveness and applicability of currently available techniques. PS globally rearranges code past basic block boundaries. Its core is a small set of simple, primitive program transformations defined in terms of adjacent nodes in a program graph. These transformations constitute the lowest level in a system of transformations and guidance rules. Higher levels of this hierarchy control and enhance the applicability of the core transformations and enable us to exploit both fine grained and coarse parallelism. Unlike other, more ad hoc approaches, PS is based on rigorous definitions of the computational model and of the core transformations. The correctness and termination of the transformations is proven

here. The completeness of the transformations is also discussed. As a result our implementation, which is now underway, can proceed on a sound basis. In particular, PS enjoys greater adaptability and independence between the levels than would be possible otherwise. This paper describes PS in detail. The correctness aspects as well as illustrations of the effectiveness of our techniques are presented. Architectures which may benefit from the use of PS are also discussed.

title: Multilevel Data Structures Models and Performance
abstract: We advocate a stepwise method of deriving high performance implementation of a set of operations. This method is based on the ability to organize the data into a multilevel data structure so as to provide an efficient implementation of all the operations. Typically, for such data organization the performance may deteriorate over a period of time and that can be corrected by reorganizing the data. This data reorganization is done by the introduction of maintenance processes. For a particular example we consider the multilevel data organization and the different models of maintenance processes possible. We sketch a correctness proof for the implementation we develop. Performance behaviour for the different models are derived and we also present some simulation studies of the performance.

title: Characterizations for Acyclic Database Schemes
abstract: Acyclic database schemes have attracted much interest because of the nice properties enjoyed by such schemes. Recently some new acyclicity conditions that are strictly stronger than the normal α-acyclicity have been introduced by Fagin. Because of increased requirements, the database schemes in the new classes have some further useful properties that are not shared by α-acyclic schemes. Therefore the new classes have practical relevance. A database designer may work in terms of attribute sets and data dependencies, and not only in terms of database schemes. Thus it is important to have a characterization for the acyclic schemes of various degree in terms of data dependencies. For α-acyclic schemes such a characterization exists, but for the new classes the question has been open. In this paper we provide characterizations for β-, γ- and Berge-acyclic database schemes. The characterizations can be stated in a simple form: thus they should be useful for the database designer.

title: Inexact Agreement: Accuracy, Precision, and Graceful Degradation
abstract: An Inexact Agreement protocol alows processors that each have a value approximating $\hat{\nu}$ to compute new values that are closer to each other and close to $\hat{\nu}$. Two fault-tolerant protocols for Inexact Agreement are described. As long as fewer than 1/3 of the processors are faulty, the protocols give the required convergence; they also permit iteration and thus convergence to any desired precision. When between 1/3 and 2/3 of the processors are faulty, the protocols may not converge. However, then processors either detect that too many faults have occurred or the new values computed by processors remain close to each other and to $\hat{\nu}$. In this case, the divergence is bounded. Use of the protocols for clock synchronization in a distributed system is explained.

title: The Semantics of Evidence
abstract: The usual meaning of a sentence in the predicate calculus is its truth value. In this paper we show that there is associated with every statement a set of elements comprising evidence for it. A statement is true in a model exactly when there is evidence for it. Proofs can be regarded as expressions which denote evidence. A statement is constructively true when the evidence can be computed from its proofs. Proofs are useful in practical computations when evidence for statements is needed. They are especially valuable in relating computations to the problems they solve.

title: FRESH: A Higher-Order Language with Unification and Multiple Results
abstract: This paper presents Fresh, a language that integrates logic programming features into higher-order functional programming. The language incorporates unification, multiple results and a collection construct. Many examples illustrate that these extensions of functional programming are useful. We define an operational semantics along the lines of Plotkin's structural approach. The semantics is of intrinsic interest since it covers backtracking and the collection construct. To illustrate the conceptual similarities

and differences between functional and logic programming, we begin with a purely functional core language and add first unification and then backtracking. With each addition we discuss the enhanced eloquence of the language and the concomitant modifications to the semantics.

title: Time-Communication Tradeoffs for Reliable Broadcast Protocols
abstract: In the Reliable Broadcast Problem, a processor disseminates a value to all other processors in a distributed system where both processors and communication components are subject to failures. Solutions to this Reliable Broadcast problem are at the heart of most fault-tolerant applications. We characterize the execution of Reliable Broadcast protocols as a function of the properties of the underlying communication network. The class of networks considered includes familiar communication structures constructed out of fully-connected point-to-point graphs, linear chains, rings, broadcast networks (such as Ethernet) and buses. We derive a protocol that implements Reliable Broadcast for any member within this class. The execution time of the protocol is a linear function of the two parameters that characterize each network instance. The hardware-software tradeoffs that are revealed between performance, resiliency and network cost offer many new alternatives previously not considered in designing fault-tolerant systems.

title: Graph Minimal Uncolorability is D_{p}-Complete
abstract: In their excellent paper, C.H. Papadimitriou and M. Yannakakis [PY] asked whether the minimal-3-uncolorability problem is, among other Critical Problems, D_{p}-complete. This paper gives an affirmative answer to the above question. We show that minimal-k-uncolorability is D_{p}-complete, for all fixed $k \geq 3$. Furthermore, for k = 3, the reduction can be modified by using "sensitive" gadgets to resolve the planar case, bounded vertex degree case and their combination.

title: On The Schur Decomposition of a Matrix for Parallel Computation
abstract: An algorithm to solve the eigenproblem for non-symmetric matrices on an $N \times N$ array of mesh connected processors, isomorphic to the architecture described by Brent and Luk for symmetric matrices, is presented. This algorithm is a generalization of the classical Jacobi method, which holds promise for parallel architectures. The rotational parameters for the non-symmetric case are carefully analyzed; many examples of a working program, simulating the parallel architecture, are given.

title: A Model and Temporal proof system for Networks of Processes
abstract: An approach is presented for modeling networks of processes that communicate exclusively through message passing. A process (or a network) is defined by its set of possible behaviors, where each behavior is an abstraction of an infinite execution sequence of the process. The resulting model is simple and modular and facilitates information hiding. It can describe both synchronous and asynchronous networks. It supports recursively-defined networks and can characterize liveness properties such as progress of inputs and outputs, termination, and deadlock. A sound and complete temporal proof system based on the model is presented. It is compositional - a specification of a network is formed naturally from specifications of its components.

title: Design-By-Example: A Design Tool for Relational Databases
abstract: In recent years, research in relational design theory and in query optimization has established a firm ground for designing well-structured logical and physical database schemes. However, the design process prequires mastering a considerable amount of theoretical results. Furthermore, even for the initiated database designer, many of the known algorithms for logical design do not provide constructive guidelines for generating a database scheme that would prevent update anomalies and data inconsistencies. Nor do the algorithms and evaluation methods for file structures and query processing provide constructive physical design rules. We propose an expert tool that would make knowledge in relational design theory and query optimization automatically and transparently available to the database designer. This tool is a system with an interactive, graphical interface that uses examples to guide the designer through several phases of logical and physical database design. Logical design is based on example relations, and physical design on example queries. The example relations are automatically generated by the system. They contain sample data and satisfy the data dependencies that the designer specifies with the assistance of the expert tool. The example queries and their expected frequency are specified by the designer, using graphically displayed skeleton queries. The system generates a physical design scheme that optimizes the mix of queries expected by the designer, and computes a performance forecast. Both example relations and example queries can be modified by the designer, until the expert tool generates a satisfactory design.

title: Analysis of Hard Real-Time Systems

abstract: In this paper we study hard real-time systems: systems where strict time deadlines have to be met. We analyze a special case as well as a general model for hard real-time systems and study pre-emptive, static, scheduling policies for a single processor. The analysis is exact and can handle any arbitrary choice of strict deadlines. For any specification of a hard real-time system, a feasible priority assignment is one where all deadlines are met. An optimal scheduling algorithm is an algorithm that always produces a feasibile priority assignment if one exists. For both the special and general model we present an optimal scheduling algorithm.

title: Reliable Communication in the Presence of Failures
abstract: We report on the design and correctness of a communication facility for a distributed computer system. The facility provides support for fault tolerant process groups in the form of a family of reliable multicast protocols that can be used both in local and wide-area networks. These protocols attain high levels of concurrency while respecting application-specific delivery ordering constraints, and have varying cost and performance that depends on the degree of ordering desired. In particular, a protocol that enforces causal delivery orderings is introduced, and shown to be a valuable alternative to conventional asynchronous communication protocols. The facility also ensures that the processes belonging to a fault tolerant process group will observe consistent orderings of events affecting the group as a whole, including process failures, recoveries, migration, and dynamic changes to group properties like member rankings. A review of several uses for the protocols in the ISIS system, which supports fault-tolerant resilient objects and bulletin boards, illustrates the significant simplification of higher-level algorithms; made possible by our approach.

title: The GENERIC Programming Language Manual
abstract: GENERIC is a programming language for the description and manipulation of integrated circuits. GENERIC works on the layout level with the designer in complete control of the layout process. To design an integrated circuit, a program is written which hierarchically describes the chip. The dynamic calling structure of the program determines the integrated circuit's hierarchical cell structure. These cells are created by special procedures called generators. Generators are capable of producing completely custom structures-they do not consist of predefined layout. In addition to the specification, GENERIC provides operators for the manipulation of integrated circuit layouts, thus enabling existing geometry to be modified. These modifications can be geometrical, topological or circuit. GENERIC is a very high level language. The language is general purpose-the VLSI aspects of the language are layered on top of the basic language as a run-time library. Since the library itself is written in GENERIC, the language is completely extensible.

title: The Potential Method for Blending Surfaces and Corners
abstract: We survey the potential method for blending implicit algebraic surfaces, summarizing and extending work previously reported. The method is capable of deriving blends for pairs of algebraic surfaces, and is guaranteed to produce blending surfaces of lowest possible degree for two quadrics in general position. We give two paradigms by which to understand the method. The first paradigm views the blends as surfaces swept out by a family of space curves. The second, more general paradigm considers the surfaces as result of deformation of a parameter space effected by substitution. The method has a general formulation based on projective parameter spaces, but is also the image under projective transformation of the simpler, affine formulation. The deformation by substitution paradigm is extended to blend blending surfaces at solid vertices without a degree penalty, under the assumption that the vertex valence has been reduced to three. It may also lead to a general solution for blending patches of algebraic surfaces that meet tangentially. A special case of this problem is solved and illustrated.

title: Some Comments on Functional Self-Reducibility and the NP Hierarchy
abstract: In Valiant [11] and Schnorr [9], concepts of "functional self-reducibility" are introduced and investigated. We concentrate on the class NP and on the NP hierarchy of Meyer and Stockmeyer [7] to further investigate these ideas. Assuming that the NP hierarchy exists (specifically, assuming that $P \stackrel{\subset}{+} NP = \sum^{P}_{1} \stackrel{\subset}{+} \sum^{P}_{2}$ we show that, while every complete set in $\sum^{P}_{2}$ is functionally self-reducible, there exist sets in $\sum^{P}_{2}$ which are not functionally self-reducible.

title: Investigations of Type Theory in Programming Logics and Intelligent Systems
abstract: Type theory has become central to computer science because it deals with fundamental issues in programming languages, in programming methodology and specification languages, in automatic theorem proving and programming logic, in natural language semantics and in the foundations of intelligent systems. At Cornell we have been studying a logical theory of types which has influenced the design of programming languages and has become the basis of an implemented program development system. This theory answers many basic questions about data types. Here we discuss three general questions about this theory: how logical types relate to domains, how they relate to sets, how they organize programming logics and the intelligent systems built around them. These issues are each of independent value, but they also arise naturally as part of a program to provide a computationally meaningful foundation to computing theory.

title: Checkpointing and Rollback-Recovery for Distributed Systems
abstract: We consider the problem of bringing a distributed system to a consistent state after transient failures. We address the two components of this problem by describing a distributed algorithm to create consistent checkpoints, as well as a rollback-recovery algorithm to recover the system to a consistent state. In contrast to previous algorithms, they tolerate failures that occur during their executions. Furthermore, when a process takes a checkpoint, a minimal number of additional processes are forced to take checkpoints. Similarly, when a process rolls back and restarts after a failure, a minimal number of additional processes are forced to roll back with it. Our algorithms require each process to store at most two checkpoints in stable storage. This storage requirement is shown to be minimal under general assumptions.

title: On Sparse Oracles Separating Feasible Complexity Classes
abstract: This note clarifies which oracles separate NP from P and which do not. In essence, we are changing our research paradigm from the study of which problems can be relativized in two conflicting ways to the study and characterization of the class of oracles achieving a specified relativization. Results of this type have the potential to yield deeper insights into the nature of relativization problems and focus our attention on new and interesting classes of languages. A complete and transparent characterization of oracles that separate NP from P would resolve the long-standing P =? NP question. In this note, we settle a central case. We fully characterize the sparse oracles separating NP from P in worlds where P = NP. We display related results about coNP, E, NE, coNE, and PSPACE.

title: Loop Quantization: Unwinding for Fine-Grain Parallelism Exploitation
abstract: Loop unwinding is a well known technique for reducing loop overhead, exposing parallelism and increasing the efficiency of pipelining. Traditional loop unwinding is limited to the innermost loop in a group of nested loops and the amount of unwinding is either fixed or has to be specified by the user, on a case by case basis. In this paper we present a general technique for automatically unwinding multply nested loops, explain its advantages over other transformation techniques and illustrates its practical effectiveness.

title: Type Theory and Concurrency
abstract: The burgeoning interest in concurrent computation has sparked an increased interest in theoretical models of concurrency. While standard sequential programming has a well-understood semantics and proof theory, the nondeterministic nature of concurrency has made a similar understanding of concurrent programming extremely difficult. Much interesting work in the field has been done, and much remains yet to be done; it is our intention in this paper to present a different kind of model of concurrency, a type-theoretic one, which we hope will shed light on reasoning about concurrency. We encode the synchronization tree model of Milner's CCS as a type in the Nuprl Type Theory. This is a constructive type theory equipped with a rich collection of inference rules for reasoning about types. We relate the equality in the type of synchronization trees with various behavioral equivalences. We also discuss the relation between the logic induced by our models and various modal logics for reasoning about concurrency.

title: Semantics of Digital Networks Containing Indeterminate Modules
abstract: We discuss a formal model based upon dataflow, usable for high-level digital hardware design, among other things. One of our goals is to give a denotational semantics for this model, which includes indeterminate modules. While it is well known that denotational semantics for networks containing only determinate modules can be simply expressed as a composition of stream functions, this aproach has previously been shown unacceptable for networks with indeterminate modules. Our approach is to devise composition rules based on modelling a network by the set of its possible behaviors, i.e., sequences of computational events, where each event is the appearance or consumption of a token on a data path. A sequence of such events is called a history and a set of such histories is called an archive. We give composition rules that allow us to derive an archive for a network from the archive of its constituents. We show how causal and operational constraints on network behavior can be inferred from the specification of archives. We also present a construction which allows us to obtain the the denotation of networks containing loops by a process of successive approximations. This construction is carried out using a construction resembling the category-theoretic notion of limit, which differs from that of more traditional domain theory.

title: A General Framework for Computing Block Accesses
abstract: A physical database system design should take account of skewed block access distributions, nonuniformly distributed attribute domains, and dependent attributes. In this paper we derive general formulas for the number of blocks accessed under these assumptions by considering a class of related occupancy problems. We then proceed to develop robust and accurate approximations for these formulas.

We investigate three clases of approximation methods, respectively based on generating functions, Taylor series expansions, and majorization. These approximations are as simple to use and far more accurate than the cost estimate formulas generated by making independence and uniformity assumptions.

title: The Complexity of Optimization Problems
abstract: Many important problems in computer science, such as CLIQUE, COLORING, and TRAVELLING SALESPERSON, arise naturally as optimization problems. Typically one considers these problems as decision procedures, which are often in NP, and one shows intractibility by showing them NP-complete. We generalize the notion of an NP problem, in a manner analogous to Valiant's class #P, by considering the optimization version of the problem itself, and we show that this idea yields a natural class of problems that we call OptP. This class allows us to make finer distinctions on the complexity of optimization problems than is possible in NP. For example, assuming P $\neq$ NP, we can show that TRAVELLING SALESPERSON is strictly harder than CLIQUE and CLIQUE is strictly harder than BIN PACKING. We then relate OptP to the class of functions computable in polynomial time with an oracle for NP, by showing that every P^{SAT} function decomposes into an OptP function followed by a polynomial-time computation. This allows us to clear up a misconception on the role of uniqueness for the problem of UNIQUELY OPTIMAL TRAVELLING SALESPERSON as considered by Papadimitriou is the 1982 FOCS conference.

title: Relations Between Diagonalization, Proof Systems, and Complexity Gaps
abstract: In this paper we study diagonal processes over time-bounded computations of one-tape Turing machines by diagonalizing only over those machines for which there exist formal proofs that they operate in the given time bound. This replaces the traditional "clock" in resource bounded diagonalization by formal proofs about running times and establishes close relations between properties of proof systems and existence of sharp time bounds for one-tape Turing machine complexity classses. These diagonalization methods also show that the Gap Theorem for resource bounded computations can hold only for those complexity classes which differ from the corresponding provable complexity classes. Furthermore, we show that there exist recursive time bounds $T(n)$ such that the class of languages for which we can formally prove the existence of Turing machines which accept them in time $T(n)$ differs form the class of languages accepted by Turing

machines for which we can prove formally that they run in time $T(n)$.

title: Some Ideas on Data Types in High Level Languages
abstract: WE explore some new and old ideas concerning data types; what a data type is, overloading operators, when and how implicit conversions between programmer data types should be allowed and so forth. The current notion that a data type is a set of values together with basic operations in that set leads us to conclude that formal parameter types need not be so explicitly stated. Given a formal parameter X with operations $o_{1},\ldots o_{n}$ being performed on X within a procedure, one should be able to supply, as actual parameter in call, a variable of any type which has operations $o_{1},\ldots o_{n}$ defined on it. We introduce a notation for this, using PASCAL as a basic language, illustrate the added flexibility it gives us, and show briefly how to implement the idea efficiently.

title: The Boolean Hierarchy: Hardware over NP
abstract: In this paper, we study the complexity of sets formed by boolean operations $(\bigcup, \bigcap,$ and complementation) on NP sets. These are the sets accepted by trees of hardware with NP predicates as leaves, and together form the boolean hierarchy. We present many results about the boolean hierarchy: separation and immunity results, complete languages, upward separations, connections to sparse oracles for NP, and structural asymmetries between complementary classes. Some results present new ideas and techniques. Others put previous results about NP and D^{P} in a richer perspective. Throughout, we emphasize the structure of the boolean hierarchy and its relations with more common classes.

title: Geometric Ambiguities in Boundary Representations
abstract: Boundary representations are usually separated into two components, a topological component and

a geometric component. The conditions necessary to insure that the topological component is unambiguous are well understood. However, in algebriac modeling systems (as opposed to polyhedral modeling systems), an unambiguous topological structure can have noncongruent geometric interpretations with identical vertex coordinates, face equations and edge descriptions using the usual representation of edges as the intersection of faces along with tangent vectors at vertices. This means that the conversion of a CSG tree that unambiguously describes a solid can lead to an ambiguous boundary representations unless additional information is retained in the boundary representation. This paper examines the source of these ambiguities and presents one method for their elimination.

title: On Estimating the Condition of Eigenvalues and Eigenvectors
abstract: A method is developed for estimating the accuracy of computed eigenvalues and eigenvectors that are obtained via certain EISPACK subroutines. It does this at a cost of $O(n^{2})$ flops per eigenpair assuming that the eigenpair is known and assuming that the original matrix has been reduced to Hessenberg form. The heart of the technique involves estimating the smallest singular value of a certain nearly triangular submatrix. This is accomplished by some standard "zero-chasing" with Hivens transformations and with a 2-norm version of the LINPACK condition estimator. An EISPACK compatible code has been developed and its performance is discussed. Suggestions for extending the current work to general invariant subspaces and to the generalized eigenvalue problem are given.

title: Enhancement of Text Representations Using Related Document Titles
abstract: Various attempts have been made over the years to construct enhanced document representations by using thesauruses of related terms, term association maps, or knowledge frameworks that can be used to extract appropriate terms and concepts. None of the proposed methods for the improvement of document representation has proved to be generally useful when applied to a variety of different retrieval environments. Some recent work by Kwok suggests that document indexing may be enhanced by using title words taken from bibliographically related items. An evaluation of the process shows that many useful content words can be extracted from related document titles, as well as many terms of doubtful value. Overall, the procedure is not sufficiently reliable to warrant incorporation into operational automatic retrieval systems.

title: A Parallel Algorithm for Large Sparse Cholesky Factorization on a Multiprocessor
abstract: We develop an algorithm for computing the symbolic and numeric Cholesky factorization of a large sparse symmetric positive definite matrix. The algorithm is intended for a message-passing multiprocessor system, such as the hypercube, and is based on the concept of elimination forests. In addition, we provide an algorithm for computing these forests along with a discussion of the algorithm's complexity and a proof of its correctness. We also examine the related issue of load balancing.

title: The Complexity of Fine Motion Planning
abstract: We study the complexity of fine motion planning for robots with position measurement and damping. A reduction from fine motion planning with position measurement only to the "classical piano mover's problem" is developed, thereby showing it to be feasible in polynomial time. We then show that deciding the existence of fine motion plans for robots with damping in three dimensional scenes is PSPACE-hard and, with a view to finding the cause for the jump in the complexity, we identify a restricted subclass of the PSPACE-hard problem that is PSPACE-complete. Finally, we show how to restrict this subclass to permit polynomial time algorithms for the problems in it.

title: A Paradigm for Reliable Clock Synchronization
abstract: Existing fault-tolerant clock synchronization protocols are shown to result from refining a single clock synchronization paradigm. In that paradigm, a reliable time source periodically issues messages that cause processors to resynchronize their clocks. The reliable time source is approximated by reading all clocks in the system and using a convergence function to compute a fault-tolerant average of the values read. The performance of a clock synchronization algorithm based on the paradigm can be quantified in terms of the two parameters that characterize the behavior of the convergence function used: accuracy and precision.

title: A Note on the Transaction Backout Problem
abstract: The transaction backout problem arises in the area of distributed databases. Suppose failures partition a data-redundant distributed database, and each partition continues to function as if it were the entire database. When the database is reconnected, the transactions executed by different partitions may not be serializable, and hence it may be necessary to back out some of the transactions. The transaction backout problem is to remove the smallest set of transactions that will leave the remaining ones serializable. The general problem is NP-complete, and in this paper we show that the special case of a fixed-size database can be solved in polynomial time by dynamic programming.

title: On the Reliability of Fault-Tolerant Distributed Computing Systems
abstract: The designer of a fault-tolerant distributed system faces numerous alternatives. Using a stochastic model of processor failure times, we investigate design choices such as replication level, protocol running time, randomized versus deterministic protocols, fault detection and authentication. We use the probability with which a system produces the correct output as our evaluation criterion. This contrasts with previous fault-tolerance results that guarantee correctness only if the percentage of faulty processors in the system can be bounded. Our results reveal some subtle and counterintuitive interactions between the design parameters and system reliability.

title: Designing Fault-Tolerant Algorithms for Distributed Systems Using Communication Primitives
abstract: Fault-tolerance is an important requirement in distributed computing systems. However, designing applications for distributed systems is a difficult task, particularly when components of the system can fail. The difficulty of this task increases with the severity of failures encountered. Arbitrary process failures are generally much harder to overcome than failures that are restricted, e.g. where processes only fail by halting. Thus, techniques that restrict the disruptive behavior of faulty processes can greatly simplify the design of fault-tolerant algorithms. Such techniques effectively provide reduction mechanisms from one class of failures to a more benign class. Message authentication is an example of a technique that imposes restrictions on the bahavior of fault processes. This technique has been used to derive simple solutions to many problems of fault-tolerance for systems with arbitrary failures. To exploit the simplicity provided by authentication we present communication primitives that provide properties of authentication without using digital signatures. These primitives can also be extended to provide properties beyond those of authentication, thereby further restricting the types of faults that have to be overcome. (ABRIDGED ABSTRACT)

title: A Parallel Ordering for the Block Jacobi Method on a Hypercube Architecture
abstract: Jacobi methods for computing the singular value decomposition are ideally suited for multiprocessor environments since they contain a great deal of inherent parallelism. We give a parallel ordering for the block Jacobi Method that allows us to take full advantage of the nearest-neighbor topology of the hypercube. It is based on recursively embedding smaller rings into the hypercube using a Gray code labelling of processor nodes. This scheme is optimal in that it entails the lowest communication overhead possible.

title: Sorting Large Files on a Backend Multiprocessor
abstract: A fundamental measure of processing power in a database management system is the performance of the sort utility it provides. When sorting a large data file on a serial computer, performance is limited by factors involving processor speed, memory capacity and I/O bandwidth. In this paper, we investigate the feasibility and efficiency of a parallel sort-merge algorithm through implementation on the JASMIN prototype,

a backend multiprocessor built around a fast packet bus. We describe the design and implementation of a parallel sort utility that may become a building block for query processing in a database system that runs on JASMIN. We present and analyze the results of measurements corresponding to a range of file sizes and processor configurations. Our results show that using current, off-the-shelf technology coupled with a streamlined distributed operating system, three and five microprocessor configurations provide a very cost-effective sort of large files. The three processor configuration sorts a 100 megabyte file in one hour, which compares well with commercial sort packages available on high-performance mainframes. In additional experiments, we investigate a model to tune our sort software, and scale our results to higher processor and network capabilities.

title: Infinite Objects in Type Theory
abstract: In this paper we show how infinite objects can be defined in a constructive type theory. The type theory that we use is a variant of Martin-Lof's Intuitionistic Type Theory. We show how one can express the intuition that infinite objects are understood through a limiting process without having to introduce partial objects in the theory. This means that we can adhere to the propositions-as-types principle. The type of infinite objects thus contains only total elements. The approximation is expressed through a sequence of types that approximate the type of infinite objects. We give two semantic accounts of types of infinite objects. The first is lattice theoretic and shows how these types can be understood as fixed points. The second is category theoretic and shows the duality between types of infinite objects and the ordinary recursive type definitions.

title: ISIS: A System for Fault-Tolerant Distributed Computing
abstract: The ISIS system transforms abstract type specifications into fault-tolerant distributed implementations, while insulating users from the mechanisms whereby fault-tolerance is achieved. This paper discusses the transformations that are used within ISIS, methods for achieving improved performance by concurrently updating replicated data, and user-level issues that arise when ISIS is employed to solve a fault-tolerant distributed problem. We describe a small set of communication primitives upon which the system is based. These achieve high levels of concurrency while respecting ordering requirements imposed by the caller.

Finally, the performance of a prototype is reported for a variety of system loads and configurations. In particular, we demonstrate that performance of a replicated object in ISIS can equal or exceed that of a nonreplicated object.

title: Complexity Classes Without Machines: On Complete Languages for UP
abstract: This paper develops techniques for studying complexity classes that are not covered by known recursive enumerations of machines. Often, counting classes, probabilistic classes, and intersection classes lack such enumerations. Concentrating on the counting class UP, we show that there are relativizations for which UP^{A} has no complete languages and other relativizations for which $P^{B} \neq UP^{B} \neq NP^{B}$ and UP^{B} has complete languages. Among other results we show that $P \neq UP$ if and only if there exists a set S in P of Boolean formulas with at most one satisfying assignment such that $S \bigcap SAT$ is not in P. $P \neq UP \bigcap coUP$ if and only if there exists a set S in P of uniquely satisfiable Boolean formulas such that no polynomial-time machine can compute the solutions for the formulas in S. If UP has complete languages then there exists a set R in P of Boolean formulas with at most one satisfying assignment so that $SAT \bigcap R$ is complete for UP. Finally, we indicate the wide applicability of our techniques to counting and probabilistic classes by using them to examine the probabilistic class BPP. There is a relativized world where BPP^{A} has no complete languages. If BPP has complete languages then it has a complete language of the form $B \bigcap MAJORITY$, where $B \in P$ and $MAJORITY = \{f | f$ is true for at least half of all assignments\} is the canonical PP-complete set.

title: The Null Space Problem II: Algorithms
abstract: The Null Space Problem is that of finding a sparsest basis for the null space (null basis) of a $t \times n$ matrix of rank t. This problem was shown to be NP-hard in Coleman and Pothen (1985). In this paper we develop heuristic algorithms to find sparse null bases. These algorithms have two phases: In the first combinatorial phase, a minimal dependent set of columns is identified by finding a matching in the bipartite graph of the matrix. In the second numerical phase, a null vector is computed from this dependent set. We describe an implementation of our algorithms and provide computational results on several large sparse constraint matrices from linear programs. One of our algorithms compares favorably with previously reported algorithms in sparsity of computed null bases and in running times. Unlike the latter, our algorithm does not require any intermediate dense matrix storage. This advantage should make

our algorithm an attractive candidate for large sparse null basis computations. A matching based algorithm is designed to find orthogonal null bases, but we present some theoretical evidence that such bases are unlikely to be sparse. Finally, we show how sparsest orthogonal null bases may be found for an n-vector and a $t \times n$ dense matric by a divide and conquer strategy. The algorithm for a dense matrix is suited for implementation on a parallel machine architecture.

title: Impact of Communciation Networks on Fault-Tolerant Distributed Computing
abstract: When the desired reliability of a computing system exceeds that of its individual hardware components the need for fault-tolerant systems arise. While distributed systems have the potential to achieve highly reliable computing, programming them is a challenging task. Several paradigms have been identified that can simplify the conceptual design of fault-tolerant distributed systems. Properties of a distributed system have profound implications on the solvability and efficiency of implementations of these paradigms. In this thesis we study the effect that different communication models have on the efficiency of fault-tolerant computing. As an instance of a fundamental operation we examine protocols for reliable broadcast in distributed systems. Our main contribution is the characterization of the time complexity of reliable broadcast with respect to communication models. A practical consequence of our results is the development of efficient reliable broadcast protocols with respect to communication models. A variety of common networks are shown to support this style of communication. In fact, by parameterizing the minimum multicast size and diameter of these networks, we are able to characterize all known network architectures. Distributed systems where processors perceive the same approximate time makes programming them much easier. Clock synchronization protocols implement this abstraction given only clocks that have bounded drift rates with respect to real time. We show how a primitive which is normally used only for communication in a distributed system can also be used for synchronizing clocks. If this primitive occurs naturally with a sufficient frequency, clock synchronization can be achieved at no additional message cost. Our results reveal hardware/software tradeoffs between performance, resiliency and network cost. Thus, they offer many new alternatives previously not considered in designing fault-tolerant systems.

title: Implementation Issues In Clock Synchronization
abstract: We present some results from an experimental implementation of a recent clocks synchronization algorithm. This algorithm was designed to overcome arbitrary processor failures, and to achieve optimal accuracy, i.e., the accuracy of synchronized clocks (with respect to real time) is as good as that specified for the underlying hardware clocks. Our system was implemented on a set of workstations on a local area braodcast network. Initial results indicate that this algorithm can form the basis of an accurate, reliable, and practical distributed time service.

title: Reliable Broadcast Protocols and Network Architecture: Tradeoffs and Lower Bounds
abstract: Reliable Broadcast is a mechanism by which a processor in a distributed system disseminates a value to all other processors in the presence of both communication and processor failures. Protocols to achieve Reliable Broadcast are at the heart of most fault-tolerant applications. We characterize the execution time of Reliable Broadcast protocols as a function of the properties of the underlying communication network. The class of networks considered includes familiar communication structures such as fully-connected point-to-point graphs, linear chains, rings, broadcast networks (such as Ethernet) and buses. We derive a protocol

that implements Reliable Broadcast for any member within this class. We present a novel proof technique to obtain lower bound results for Reliable Broadcast in this environment. This proof technique is based on graph mappings. The hardware-software tradeoffs that are revealed between performance, resiliency and network cost offer many new alternatives previously not considered in designing fault-tolerant systems.

title: Extracting Efficient Code From Constructive Proofs
abstract: Extraction is a technique for producing verified programs. A proof of $\forall chi : T \ldot \exists y : T' \ldot F$ corresponds to a function f of type $T \rightarrow T'$ that maps every χ of type T to a y of type T' such that F is true. If the proof is constructive, then f is recursive. The semantics of extracted code involves the manipulation of justifications, which are pieces of evidence for the truth of formulas. The raw extracted code for the formula above is actually a function γ that maps χ to a pair (y, γ'), where γ' is a justification that provides evidence for the truth of F. This thesis presents various ways to improve the efficiency of extracted programs. The first way uses traditional code optimizations. Though very helpful, they are no panacea. The second way involves small changes to its underlying semantics. Certain formulas, called singleton formulas, have no interesting justifications; if F is such a formula, no justification for it needs to be built, which simplifies the extracted code. The third way to improve extracted code is to add call-by-reference parameters to it. As originally defined, extracted code passes arguments by value, which leads to inefficient code for mutable objects like arrays: passing an array by value requires making a copy of it. Adding call-by-reference parameters entails adding a state to the semantics of extracted code, which in turn leads to various semantic and syntactic design issues, like aliasing and side-effects. To account for these changes, the constructive logic used to build proofs is modified. A proof of quicksort illustrates the functional, assignment-free, side-effect-free style of proof promoted by the new logic. To relieve the user of some of the mental overhead involved in using the new logic, an array

inferencing algorithm is presented. The algorithm allows users to get code that uses arrays from proofs that reason about and manipulate lists in restricted ways. In this way, users can view the use of arrays as an optimization.

title: The Geometry of Projective Blending Surfaces
abstract: Blending surfaces smoothly join two or more primary surfaces that otherwise would intersect in edges. We outline the potential method for deriving blending surfaces, and explain why the method needs to be considered in projective parameter space, concentrating on the case of blending quadrics. Let W be the quadratic polynomial substituted for the homogenizing variable of parameter space. We show that a blending surface derived in projective parameter space is the projective image of a different blending surface derived in affine parameter space, provided that $W = U^{2}$ for some linear U. All blending surfaces may therefore be classified on basis of the projective classification of W.

title: Exact Counting is as Easy as Approximate Counting
abstract: We show that exact counting and approximate counting are polynomially equivalent. That is $P^{#P} = P^{Approx#P}$, where #P is a function that computes the number of solutions to a given Boolean formula f (denoted by $|| f ||$), and Approx#P computes a short list that contains $|| f ||$. It follows that if there is a good polynomial time approximator for #P (i.e., one where the list has at most $O(|f|^{1-\epsilon})$ elements), then $P = NP = P^{#P}$ and probabilistic polynomial time equals polynomial time. Thus we have strong evidence that #P cannot be easily approximated.

title: A Chordal Preconditioner for Large Scale Optimization
abstract: We propose an automatic preconditioning scheme for large sparse numerical optimization. The strategy is based on an examination of the sparsity pattern of the Hessian matrix: using a graph-theoretic heuristic, a block diagonal approximation to the Hessian matrix is induced. The blocks are submatrices of the Hessian matrix; furthermore, each block is chordal. That is, under a positive definiteness assumption, each block can be Cholesky factored without creating new nonzeroes (fill). Therefore the preconditioner is space efficient. We conduct a number of numerical experiments to determine the effectiveness of the preconditioner in the context of a linear conjugate gradient algorithm for optimization.

title: Computation of Aliases and Support Sets
abstract: When programs are intended for parallel execution it becomes critical to determine whether the evaluations of two expressions can be carried out independently. We provide a scheme for making such determinations in a language with higher order constructs and imperative features. The heart of our scheme is a mechanism for computing the support of an expression, i.e. the set of global variables involved in its evaluation. This computation requires knowledge of all the aliases of an expression. The inference schemes are presented as abstract semantic interpretations. We prove the soundness of our estimates by establishing a correspondence between the abstract semantics and the standard semantics of the programming language.

title: Some Nested Dissection Order is Nearly Optimal
abstract: The minimum fill problem is to reorder the rows and columns of a given sparse symmetric matrix so that its triangular factor is as sparse as possible. Equivalently, it is to find the smallest set of edges whose addition makes a given undirected graph chordal. The problem is known to be NP-complete, and no polynomial-time approximation algorithms are known that provide any nontrivial guarantee for arbitrary graphs (matrices), although some heuristics perform well in practice. Nested dissection is one such heuristic. In this note we prove that every graph with a fixed bound on vertex degree has a nested dissection order that achieves fill within a factor of $O(\logn)$ of minimum. This does not lead to a polynomial-time approximation algorithm, however, because the proof does not give an efficient method for finding the separators required by nested dissection.

title: On Algebraic Surfaces Meeting with Geometric Continuity
abstract: An increasingly prominent area of computer science is Computer Aided Geometric Design or CAGD. The main task of CAGD is to automate, to the greatest extent possible, the process of designing physical objects. A designer typically models an object as a collection of surfaces. For many objects, design specifications indicate only a few critical surfaces, with the remaining surfaces to be chosen so as to make the surface of the resulting object smooth. Smoothness is important because, in many mechanical objects, sharp edges are undesirable for functional or aesthetic reasons. For example, sharp edges on the interior surface of a gate valve retard fluid flow. Automatically calculating these remaining surfaces, called blending surfaces is an important task in any CAGD system. Therefore, an understanding of the mathematics of surfaces that meet smoothly is fundamental to CAGD. Specifically, this thesis investigates the following problem: given a surface V and a point or curve W on that surface, construct surfaces that meet with V with a specified degree of smoothness along W. Working from a measure of smoothness known as geometric continuity, the first half of this thesis establishes that the space of all surfaces meeting V with the k-th order geometric continuity along W is directly related to certain algebraic structures called ideals. For example, let Z(M) (the set of point for which a polynomial M is zero) be an irreducible surface that intersects another surface Z(N) transversally (nontangentially) in an irreducible curve Z(M) $\frown$ Z(N). It is shown that a surface Z(F) meets Z(M) with order k geometric continuity along Z(M) $\frown$ Z(N) if and only if F is a polynomial of the form $AM = BN^{k+1}$ where A and B are free polynomials and A is nonzero on Z(M) $\frown$ Z(N). The second half of this work applies these results to the problem of generating blending surfaces. Using the geometric properties of blending surfaces, it is shown that any surface Z(F) that smooths the intersection of two surfaces Z(M) and Z(N) must have certain algebraic properties. In particular, the degree of F must be greater than or equal to the maximum of the degrees of M^{2} and N^{2}. Finally, existing methods for constructing blending surfaces are shown to be consistent within the above algebraic framework. In fact, we demonstrate that these distinct methods are instances of a single general method for generating blending surfaces. Moreover, this general method is shown to generate blending surfaces of the lowest possible degree.

title: Deterministic Polynomial Time O(log n) Queries
abstract: $P^{NP[\log n]}$ is the class of languages recognizable by determining polynomial time machines that make $O(\log n)$ queries to an oracle for NP. Many of the languages related to optimal solution sizes of NP optimization problems are members of this class. We relate $P^{NP[\log n]}$ to the study of sparse oracles for NP by showing that if NP has a sparse $\leq^{P}_{T}$-complete set, then the polynomial time hierarchy collapses to $P^{NP[\log n]}$. We also discuss complete problems and show that UOCSAT, the set of CNF formulas with the property that every assignment that satisfies the maximum number of clauses satisfies the same set of clauses, is $\leq^{P}_{m}$-complete for $P^{NP[\log n]}$.

title: Programming with Shared Bulletin Boards in Asynchronus Distributed Systems
abstract: We consider loosely coupled distributed computing systems in which processes interact through shared resources, which are modeled as bulletin boards. The first part of the paper formalizes the notion

of consistent behavior when unreliable processes concurrently access a bulletin board. This model is interesting both as a tool for showing the correctness of a board implementation and also because it provides a mechanism for reasoning about consistency in distributed systems, which was previously lacking. The remainder of the paper discusses software techniques for implementing consistent bulletin boards in a network of processors lacking shared memory. Applications for our approach range from asynchronous interprocess communication to mechanisms for achieving mutual exclusion, deadlock detection and for building distributed database systems.

title: Polynomial Decomposition Algorithms
abstract: In a recent paper [BZ], Barton and Zippel examine the question of when a polynomial $f(x)$ over a field of characteristic 0 has a nontrivial decomposition $f(x)=g(h(x))$. They give two exponential-time algorithms, both of which require polynomial factorization. We present an $O(s^{2}r\logr)$ algorithm, where r=deg g and s =deg h. The algorithm does not use polynomial factorization. We also show that the problem is in NC. In addition, we give a new structure theorem for testing decomposibility over any field. We apply this theorem to obtain an NC algorithm for decomposing irreducible polynomials over finite fields and a subexponential algorithm for decomposing irreducible polynomials over any field.

title: On Moving and Orienting Objects
abstract: Many problems arising in the area of robotics are directly or indirectly related. In order to analyze such problems, it is necessary to incorporate the dynamics with the geometry in the mathematical formulation. With this in view, this thesis deals with two such problems - motion planning in the presence of uncertainty and the automated design of parts orienters. Motion planning for robots with errors in position measurement, velocity and time is considered and shown to be decidable in polynomial time for a large class of inputs. The robot model is then extended to include damping - a limited form of force sensing. Motion planning for point objects in three-dimensional scenes and robots with damping is shown to be PSPACE-hard. A simplified version of the same problem is shown to be PSPACE-complete. The problem of the automated design of parts orienters is rather closely related to motion planning. But the dynamics of the problem is so dominant that similar general formulations seem impossible. In this thesis, the alternative pursued is paradigm-by-paradigm analysis. Three paradigms are presented and analyzed - the “belt”, for orienting convex polygons that are infinite in the third dimension, the “pan handler”, for flat polygonal objects and

the vibratory track for flat, convex polygons. Polynomial time algorithms are developed for the automated design of orienters in each of the paradigms.

title: Resource Bounded Kolmogorov Complexity, A Link Between Computational Complexity and Information Theory
abstract: The resource bounded Kolmogorov complexity classes identify finite strings (and by extension infinite strings) according to how much we can compress and then recover the strings in a space or time bounded environment. We view the resource bounded Kolmogorov complexity classes as a link between computational complexity and information theory. Firstly, we study these classes with respect to information theory (or unbounded Kolmogorov complexity classes). Most of what we know about information theory can also be shown in a space bounded environment. Whether it also stands in a time bounded environment is an interesting problem and parallels open questions about the power of nondeterminism. Then, we investigate the structure of the classes and show the analogies and differences with the structure of computational complexity classes. For example, we build hierarchies paralleling the time and space hierarchies. We show that the exponential hierarchy collapses if and only if our parallel hierarchy collapses. Lastly, we analyse the statistical properties of random strings. Martin-Lof has shown that all strings with no short description possess all the computable statistical properties of random strings. We show that this result carries over to the space bounded Kolmogorov random strings, which pass all statistical tests using less space than the space bound. Also, allowing a little more space, we can design a test to detect all those strings. These results are further applied to the theory of pseudo-random number generators. Among other consequences, it is shown that there are some properties that no space bounded random number generator can possess. The notion of statistical tests is compared to the notion of a good pseudo-random number generator, as defined by Andrew Yao.

title: The Sky is Falling: The Strong Exponential Hierarchy Collapses
abstract: This paper investigates the complexity of the high levels of the exponential hierarchy [HY84,HIS85]: Are they hard, and if so why are they hard? We show that $P^{NE} = NP^{NE}$. From this we conclude that the strong exponential hierarchy collapses: $P^{NE} = NP^{NE} \bigcup NP^{NP^{NE}} \bigcup NP^{NP^{NP^{NE}}} \bigcup \cdots,$ where NE is nondeterministic exponential time. This suprising result, a nontrivial hierarchy collapse, is based on P^{NE} overmastering the NP^{NE} computation tree by computing better and better partial census information. We note why the combinatorics involved prevents us from similarly proving that the polynomial hierarchy collapses. Next we look at the exponential hierarchy, which is NE given a rich database: $NE \bigcup NE^{NP} \bigcup NE^{NP^{NP}} \bigcup \cdots$. We show that if the exponential hierarchy's Δ_{i} and Σ_{i} levels do separate, this is due not to the power of the database but to the extravagant number of queries NE makes to the database. Thus the high levels of the strong exponential hierarchy are no harder than the low levels. The high levels of the exponential hierarchy separate completely only if NE floods its database with queries. Extending our techniques, we derive sufficient conditions for collapsing complexity classes, and use them to generate strong new quantitative relativization results.

title: On Some Most Probable Separations of Complexity Classes
abstract: This thesis is a study of separations of some complexity classes which take place in almost all relativized worlds. We achieve probability one separations of PSPACE from the Polynomial-time Hierarchy PH. Also we separate with probability one all levels of the Boolean Hierarchy BH. The study on the Boolean Hierarchy is a continuation of the work by Bennet and Gill in [BG81] and the joint work in [CH86], where we introduced the "sawing" argument. This "sawing" technique is adapted here to yield probability one separation. The study on PSPACE versus the Polynomial-time Hierarchy is more intriguing. Several novel techniques are employed here. The connection with Boolean circuit is exploited to reduce the problem to a Boolean circuit computation problem. The fixed depth unbounded fan-in Boolean circuit model is considered in connection with the parity function. We show that with an exponential bound of the form $exp(n^{\ lambda}$ on the size of the circuits, they make asymptomatically 50% error on all possible inputs, uniformly. Certain probabilistic and game theoretic methods are applied extensively to conclude the result.

title: Constructive Automata Theory Implemented with the Nuprl Proof Development System
abstract: The Nuprl proof development system was designed for the computer-assisted problem solving in mathematics and programming. In particular it can be used for the development of mathematical proofs and of programs which are guaranteed to meet their specifications. The implementation of the theory of finite automata gave lots of insights into its strengths and weaknesses and shows that Nuprl is indeed powerful enough now to obtain nontrivial results within reasonable amounts of time. Its success shall encourage people to actually use the system and build theories within it. This report describes the techniques and the user-defined extensions to the Nuprl object language which were necessary to formulate and prove theorems from the theory of finite automata. It also describes the experiences which came from actually working with the current Nuprl system and gave some useful insights into its strenghts and weaknesses. A complete Nuprl-proof of the pumping lemma and its computational evaluation are presented and an outline for future development is given.

title: Efficient Concurrency Control for Libraries of Typed Objects
abstract: Concurrency control algorithms use a conflict detection strategy to determine operations that have to be delayed to provide a correct serialization order. To keep the cost of detecting conflicts feasible, most algorithms employ rather crude strategy that sometimes delays operations when in reality they could proceed concurrently. In an object oriented system where calls to objects can be nested this problem is exacerbated by the fact that a concurrency control decision is made at each level in the calling hierarchy. In this dissertation we address concurrency control issues in object oriented systems. We develop a model of execution for operations on objects, drawing on similar models developed for database systems. We propose a new serialization algorithm that keeps a partial history of operations at each site, and exploits semantic knowledge of operations to achieve a finer granularity of conflict detection. Conflict detection is based on user supplied conflict predicates, thus giving the user the option of fine grained concurrency control and the responsibility for the level of cost of the conflict detection strategy. We then show how to implement the algorithm in a distributed system where sites can fail and recover independently. Finally, we explore techniques to reduce the message overhead and latency for the algorithm in a distributed system.

title: Sparse Partial Pivoting in Time Proportional to Arithmetic Operations
abstract: Existing sparse partial pivoting algorithms can spend asymptomatically more time manipulating data structures than doing arithmetic, although they are tuned to be efficient on many large problems. We present an algorithm to factor sparse matrices by Gaussian elimination with partial privoting in time proportional to the number of arithmetic operations. Implementing this algorithm requires only simple data structures and gives a code that is competitive with, and often faster than, existing sparse codes. The key idea is a new triangular solver that uses depth-first search and topological ordering to take advantage of sparsity in the right-hand side.

title: Output-Size Sensitive Algorithms for Constructive Problems in Computational Geometry
abstract: In computer science the efficiency of algorithms is usually measured in terms of the size of the input. The output size, on the other hand, has been used for this purpose rather infrequently, except in certain enumerative query problems. This thesis deals with several constructive (in constrast to query) problems in

computational geometry and presents algorithms whose running time depends non-trivially on the output size. We present an algorithm that finds the convex hull on n points in the plane in worst case time $O(n \log H)$, where H is the number of points that turn out to be vertices of the convex hull. we examine the d-dimensional maximal vector problem and show that as long as V, the number of maximal vectors in a set, is not too large, these maximal vectors can be found in $O(n \log V)$. We present an algorithm for solving the planar convex subdivision overlay problem in time proportional to the combined input and output size. Finally we show that, after some preprocessing in the form of linear programs, d-dimensional convex hulls can be constructed at logarithmic cost per face.

title: Substituting for Real Time and Common Knowledge in Distributed Systems
abstract: We study time and knowledge in synchronous and asynchronous reliable distributed systems. For both types of systems, we describe clocks that can be used as if they were perfectly synchronized real-time clocks in the solution of a large class of problems that we formally characterize. For this same class of problems, we also propose a broadcast primitive that can be used as if it achieves common knowledge. Our clocks and broadcast primitive are tools that considerably simplify the task of designing and proving correct distributed algorithms: the designer can assume that processors have access to real-time clocks and the ability to achieve common knowledge. The latter can be used to implement the abstraction of shared memory.

title: (Almost) No Cost Clock Synchronization
abstract: We show how synchronized clocks can be realized in a distributed system as a byproduct of a common communication paradigm where processors periodically perform broadcasts. Our approach decouples the precision concern-limiting how much correct clocks can differ from each other-and the accuracy concern-limiting how much any correct clock can differ from real time-of clock synchronization. Given a system that guarantees only precision, we develop a protocol whereby high accuracy can be achieved on demand. In this manner, the "lazy" protocol we obtain incurs the cost of high accuracy only when needed while keeping the basic synchronization procedure extremely simple and cheap.

title: A Fine-Grain Parallelizing Compiler
abstract: Percolation Scheduling (PS) is a new technique for compiling programs into parallel code. It attempts to overcome problems that limit the effectiveness and applicability of currently available techniques. PS globally rearranges code past basic block boundaries. Its core is a small set of simple, primitive program

transformations defined in terms of adjacent nodes in a program graph. These transformations constitute the lowest level in a system of transformations and guidance rules. Higher levels of this hierarchy control and enhance the applicability of the core transformations and enable us to exploit both fine grained and coarse parallelism. Unlike other, more ad hoc approaches, PS is based on rigorous definitions of the computational model and of the core transformations. The correctness and termination of the transformations is proven here. The completeness of the transformations is also discussed. As a result our system implementation can proceed on a sound basis. In particular, PS enjoys greater adaptability and independence between the levels than would be possible otherwise. This has greatly facilitated the implementation of the first prototype version of our compiler, which is now complete. This paper describes PS in detail. The correctness aspects as well as illustrations of the effectiveness of our techniques are presented. Architectures which may benefit from the use of PS are also discussed.

title: On Ranking
abstract: This paper structurally characterizes the complexity of ranking. A set is P-rankable if there is a polynomial time computable function f so that for all $x, f(x)$ computes the number of elements of A that are lexicographically $\leq x$, i.e., the rank of x with respect to A. We'll say a class C is P-rankable if all sets in C are P-rankable. Our main results show that with the same certainty with which we believe counting to be complex, and thus with at least the certainty with which we believe P $\neq$ NP, we may believe that P has no ranking functions of any type - uniform, strong, weak, or approximate. We show that: P and NP are equally likely to be P-rankable. P is P-rankable if and only if $P = P^{#P}$. This extends important work of Blum and Sipser [Sip85]. Even weak variations of P-ranking are hard if $P \neq P^{#P}$. PSPACE is P-rankable if and only if P = PSPACE. If P has small ranking circuits, then it has small ranking circuits of relatively low complexity. If P has small ranking circuits then the power of counting falls into the polynomial hierarchy (i.e., $P^{#P} \subseteq \(\sum_{2}^{p})\ = PH$). P/poly, the class of sets with small circuits is not P-rankable. P/poly has small ranking circuits if and only if $P^{#P}$/poly = $P^{#P/poly}$ = P/poly. If P is rankable, then P/poly has small ranking circuits. This links the ranking complexity of uniform and nonuniform classes. The ranks of some strings in easy sets are of high relative time-bounded Kolmogorov complexity unless P = $P^{#P}$. It follows that even approximate ranking is hard unless P = $P^{#P}$. This partially resolves a question posed by Sipser [Sip85, pp. 447-448].

title: Can P and NP Manufacture Randomness?
abstract: This paper studies how Kolmogorov complexity dictates the structure of standard deterministic and nondeterministic classes. We completely characterize, in Kolmogorov terms, when $P^{NP[\log]}= P^{NP}$,

where [log] indicates that $O(\log n)$ oracle calls are made. We give a Kolmogorov characterization of P=NP that links the work of Adleman and Krentel. Briefly stated, complexity classes collapse unless they can manufacture randomness. A Δ^{p}_{2} machine is a P machine with an NP oracle. The series of replies the NP oracle makes is called the pronouncement. We show that $P^{NP[\log]}= P^{NP}$ if and only if each Δ^{p}_{2} language is accepted by some Δ^{p}_{2} machine with Kolmogorov simple pronouncements. (i.e., $(\forall P_{i}) (\exists c) (\forall x) [Pronouncements_{P_{i}}$ SAT $(x) \in K[c \log n, n^{c} | x]])$. Turning to functions, we show that: $P^{NP[\log]}F = P^{NP}F$ if and only if all Δ^{p}_{2} machines have Kolmogorov simple pronouncements. Since $P^{NP[\log]}F = P^{NP}F \Longleftrightarrow$ P=NP (Krentel), the above gives an alternate Kolmogorov characterization of the P=NP question, which complements Adleman's classic characterization. Our key technique is an oracle-based divide and conquer over a tree of potential pronouncements. The results generalize to many other classes, including truth-table classes and counting classes. Thus, Kolmogorov complexity dictates the structure of the classes that are at the center of our understanding of feasible computation.

title: A Block or Factorization Scheme for Loosely Coupled Systems of Array Processors
abstract: A statically scheduled parallel block QR factorization procedure is described. It is based on "block" Givens rotations and is modeled after the Gentleman-Kung systolic QR procedure. Independent tasks are associated with each block column. "Tallest possible" subproblems are always solved. The method has been implemented on the IBM Kingston LCAP-1 system which consists of ten FPS-164/MAX array processors that can communicate through a large shared bulk memory. The implementation revealed much about the tradeoff between block size and load balancing. Large blocks make load balancing more difficult but give better 164/MAX performance and less shared memory traffic. The results obtained indicate that our approach to parallelizing the QR factorization is competitive for very large problems, e.g. of the order 5000-by-1000.

title: A Parallel Graph Partitioning Algorithm for a Message-Passing Multiprocessor
abstract: We develop a parallel algorithm for partitioning the vertices of a graph into $p \geq 2$ sets in such a way that few edges connect vertices in different sets. The algorithm is intended for a message-passing multiprocessor system, such as the hypercube, and is based on the Kernighan-Lin algorithm for finding small edge separators on a single processor. We use this parallel partitioning algorithm to find orderings

for factoring large sparse symettric positive definite matrices. These orderings not only reduce fill, but also result in good processor utilization and low communication overhead during the factorization. We provide a complexity analysis of the algorithm, as well as some numerical results from an Intel hypercube and a hypercube simulator.

title: Integration Constraints in Parametric Design of Physical Objects
abstract: Design by constraint is a powerful approach to improve CAD systems and designer productivity. This paper addresses the topic of incorporating integration constraints concerning object mass and inertia in a CAD system. Two classes of generic objects are discussed that contain affine and conformal images of a given solid, usually derived from the initial design solution. Domain-derivatives are partial derivatives needed to solve the existence problem of an object instance satisfying all constraints and, eventually, to find an optimal design solution. In the paper, it is shown that these derivatives are closely linked to the topology of the solid. They are symbolically expressable as integrals over domains having a lower geometrical dimension than the original solid.

title: Size-Time Complexity of Boolean Networks for Prefix Computations
abstract: The prefix problem consists of computing all the products $x_{0}x_{1}\ldots x_{j} (j=0,\ldots,N-1)$, given a sequence $X = (x_{0},x_{1},\ldots,x_{N-1})$ of elements in a semigroup. In this paper we completely characterize the size-time complexity of computing prefixes with boolean networks, which are synchronized interconnections of boolean gates and one-bit storage devices. This complexity crucially depends upon a property of the underlying semigroup, which we call cycle-freedom (no cycle of length greater than one in the Cayley graph of the semigroup). Denoting by S and T size and computation time, respectively, we have $S = \Theta((N/T) \log(N/T))$, for non-cycle-free semigroups, and $S = \Theta((N/T)$, for cycle-free semigroups. In both cases, $T \in [\Omega(\logN),O(N)]$.

title: Low-level programming for a massively parallel fine-grain computer: the Microflow approach
abstract: A new programming language MFL^{3} is described, which, while low level, combines both message passing and shared memory models. We examine both the programming style and implementation issues of such a language. The programming style splits the computation into a computation thread (one process per processor) and several server threads. The computation thread (which performs the bulk of the computation) is deterministic, while all of the non-deterministic code is in the server threads. Also described are several ways of making programming in message passing languages less tedious and more modular, in terms of compilation techniques, runtime structures and a new programming structure.

title: Epochs
abstract: To date, the implementation of message passing languages have required the communications variables (sometimes called ports) either to be limited to the number of physical communications registers in the machine, or to be mapped to memory. Neither solution is satisfactory. Limiting the number of variables decreases modularity and efficiency of parallel programs. Mapping variables to memory increases the cost of communications and the granularity of parallelism. We present here a new programming language construct called epochs. Epochs are a scoping mechanism within which the programmer can declare communications variables, which are live only during the scope of that epoch. To limit the range of time a register has to be allocated for a communications variable, the compiler ensures that all processors enter an epoch simultaneously. The programming style engendered fits somewhere between the SIMD data parallel and MIMD process spawning models. We describe an implementation for epochs including an efficient synchronization mechanism, means of statically binding registers to communications variables and a method of fusing epochs to reduce synchronization overhead.

title: A New Language - Independent Prettyprinting Algorithm
abstract: An algorithm for prettyprinting using word wrapping is described that is independent of the language being formatted and is substantially simpler than other published algorithms. The algorithm makes use of a simple model with a small set of primitives to direct the prettyprinting of text. For an input string of length n, and an output device m characters wide the algorithm runs in $O(n)$ time and requires $O(m)$ space. The algorithm can be restarted from an intermediate point and is therefore well suited for incremental prettyprinting of text. This algorithm is now being used in the Cornell Synthesizer Generator [2]. The algorithm is compared with and contrasted to the previously published algorithm by Oppen [1].

title: Dense Patch-oriented Matrix Factorization on a Hypercube Multiprocessor
abstract: We develop algorithms for Cholesky factorization and the solution of triangular systems of linear equations on a hypercube multiprocessor. Specifically, we describe algorithms that apply when the matrix is distributed around the hypercube by submatrices, or patches. We show that these algorithms use asymptomatically less internode communication than more common row- and column- oriented algorithms. Empirical results accompany the analysis and show that patch-oriented algorithms are competitive with, but not demonstrably superior to, the other algorithms for hypercubes of low dimension. Implementations in C appear in an appendix.

title: I-Structures: Data Structures for Parallel Computing
abstract: It is difficult simulteneously to achieve elegance, efficiency and parallelism in functional programs

that manipulate large data structures. We demonstrate this through careful analysis of program examples using three common functional data-structuring approaches - lists using Cons and arrays using Update (both fine-grained operators), and arrays using make-array (a "bulk" operator). We then present I-structures as an alternative, defining precisely the parallel operational semantics of Id, a language with I-structures. We show elegant, efficient and parallel solutions for the program examples in Id. I-structures make the language non-functional, but do not raise determinancy issues. Finally, we show that even in the context of purely functional languages, I-structures are invaluable for implementing functional data abstractions.

title: Exploiting Virtual Synchrony in Distributed Systems
abstract: We describe applications of a new software abstraction called the virtually synchronous process group. Such a group consists of a set of processes that cooperate to implement some distributed behavior in an environment where events like broadcasts to the group as an entity, process failures, and process recoveries appear to occur synchronously. The utility of this approach is illustrated by solving a number of classical problems using our methods. Many are problems that are quite difficult in the absence of some sort of support, and all are easily solved in the context of the mechanisms we propose here. We then describe a new version of the ISIS system, which is based on this abstraction. $ISIS_{2}$ provides a number of high level mechanisms that facilitate the use of process groups in application software design, including addressing support for atomic communication with the members of a single or several groups (even when their membership is changing), group RPC constructs, a package of distributed programming tools, a fault-tolerant asynchronous bulletin board mechanism, and resilient objects.

title: A New Method for Solving Triangular Systems on Distributed Memory Message-Passing Multiprocessors
abstract: Efficient triangular solvers for use on message passing multiprocessors are required, in several contexts, under the assumption that the matrix is distributed by columns (or rows) in a wrap fashion. In this paper we describe a new efficient parallel triangular solver for this problem. This new algorithm is based on the previous method of Li and Coleman [1986] but is considerably more efficient when $\frac{n}{p}$ is relatively modest, where p is the number of processors and n is the problem dimension. A useful theoretical analysis is provided as well as extensive numerical results obtained on an Intel iPSC with $p \leq 128$.

title: A Graphical, Language-Based Editor for Generic Solid Models Represented by Constraints.
abstract: A solid model is a representation of the space occupied by a rigid object. A generic solid (or "generic") expresses the solid models for a class of similar objects, or equivalently, a non-rigid object. Automated manufacturing systems require solid models of the objects with which they work. For example, solid models are needed to discover collision-free paths for robot arms. Previously, generics have been created

using clumsy textual languages, and solid models have usually been created using graphical editors. This thesis describes a technique for editing generics graphically, thus decreasing the labor required to create both generics and solid models. This thesis introduces microCOSM, a language for specifying solid models and generics in which a solid or generic is represented by its parts along with constraints that the parts must satisfy. Relationships between parts of an object are expressed as constraints between those parts. As a result, microCOSM can express more such relationships than current generic solid languages. A graphical editor for two-dimensional generics in microCOSM has been written. The microCOSM language and the user interface and implementation of the editor are described, and some improvements that should be made to the editor are discussed. The microCOSM editor, like any constraint-based editor, must have a constraint solver, a module that forces any object displayed by the editor to satisfy its constraints. This thesis shows why the usual techniques for solving constraints do not work well with microCOSM and show that the constraints in microCOSM are best solved as a related minimization problem. The minimization problem is chosen to achieve a harmonious compromise between the numerical complexity of the problem and the principle of least astonishment. Most bugs in microCOSM generic definitions involve having too many or too few constraints on some part of the solid. Algorithms are presented that detect under and overconstraint, under some reasonable assumptions about the constraints. These algorithms are dynamic; it is possible to determine if a modification induces an error without rerunning the entire computation. Error messages can be updated interactively, easing identification of the erroneous constraints.

title: Definability with Bounded Number of Bound Variables
abstract: A theory satisfies the k-variable-property if every first-order formula is equivalent to a formula with at most k bound variables (possibly reused). Gabbay has shown that a fixed time structure satisfies the k-variable property for some k if and only if there exists a finite basis for the temporal connectives over that structure. We give a model-theoretic method for establishing the k-variable property, involving a restricted Ehrenfeucht-Fraisse game in which each player has only k pebbles. We use the method to unify and simplify results in the literature for linear orders. We also establish new k-variable properties for various theories of bounded-degree trees, and in each case obtain tight upper and lower bounds on k. This gives the first finite basis theorems for branching-time models.

title: The Computational Behaviour of Girard's Paradox
abstract: In their paper "Type" Is Not a Type, Meyer and Reinhold argued that serious pathologies can result when a type of all types is added to a programing language with dependent types. Central to their argument is the claim that by following the proof of Girard's paradox it is possible to construct in their calculus $\lambda^{\tau \tau}$ a term having a fixed-point property. Because of the tremendous amount of formal detail involved, they were unable to establish this claim. We have made use of the Nuprl proof development system in constructing a formal proof of Girard's paradox and analysing the resulting term. We can show that the term does not have the desired fixed-point property, but does have a weaker form of it that is sufficient to establish some of the results of Meyer and Reinhold. We believe that the method used here is in itself of some interest, representing a new kind of application of a computer to a problem in symbolic logic.

title: Loop Quantization: an Analysis and Algorithm
abstract: Loop unwinding is a well-known technique for reducing loop overhead, exposing parallelism, and increasing the efficiency of pipelining. Traditional loop unwinding is limited to the innermost loop of a set of nested loops and the amount of unwinding is either fixed or must be specified by the user. In this paper we present a general technique, loop quantization, for unwinding multiple nested loops, explain its advantages over other transformations, and illustrate its practical effectiveness. An abstraction of nested loops is presented which leads to results about the complexity of computing quantizations and an algorithm.

title: Partial Objects in Constructive Type Theory
abstract: Constructive type theories generally treat only total functions; partial functions present serious difficulties. In this paper, a theory of partial objects is given which puts partial functions in a general context. Semantic foundations for the theory are given in terms of a theory of inductive relations. The domain of convergence of a partial function is exactly characterized by a predicate within the theory, allowing for abstract reasoning about termination. Induction principles are given for reasoning about these functions, and comparisons are made to the domain theoretic account of LCF. Finally, an undecidability result is presented to suggest connections to a subset of recursive function theory.

title: Load Balanced FFT Implementations on the Intel iPSC
abstract: Two implementations of both the Cooley-Tukey and Gentelman-Sande radix-two FFT algorithms are described where the distribution of computational work among the processors is balanced, i.e. every processor does the same number of complex multiplications and additions. One method requires no extra storage space for the buffering of the complex data that is to be exchanged between processors therefore allowing "in-place" computation. The second implementation is useful for doing FFT's of symmetric sequences and an example of its use in the sine transform is presented. We also show how to simulate the second implementation in terms of the first to gain "in-place" computation without the need for buffering

and intra-processor swapping.

title: Adaptive Locking
abstract: Adaptive locking is a new concurrency control scheme for relational database systems. An adaptive

locking scheduler automatically issues to each transaction appropriate locks on its read and write sets. The read and write sets of transactions are exactly the parts of the shared database that it is necessary and sufficient to lock in order to prevent all state and view inconsistencies. This paper shows how to compute logical expressions representing the read and write sets of access statements and describes an efficient algorithm to check whether the locks issued to different transactions cause them to conflict. The algorithm is based on extended tableaux capable of representing all conjunctive queries. The paper discusses how to use adaptive locking with complex queries and compares the new scheme to conventional locking. A prototype database system demonstrating how an adaptive locking scheduler reasons about conflict is presented.

title: A Non-Type-Theoretic Definition of Martin-Lof's Types
abstract: It is possible to make a natural non-type-theoretic reinterpretation of Martin-Lof's type theory. This paper presents an inductive definition of the types explicitly defined in Martin-Lof's paper, Constructive Mathematics and Computer Programming. The definition is set-theoretically valid, and probably will be convincing to intuitionists as well. When this definition is used with methods set out in the author's thesis, the inference rules presented in Martin-Lof's paper can be shown to be valid under the non-type-theoretic interpretation. This interpretation is non-trivial, that is, there are both inhabited types and empty types, and so, validity entails simple consistency. Finally, Michael Beeson has defined some recursive realizability models which we shall compare with the term model presented here, and we shall compare the methods of definition.

title: Incremental Graph Evaluation
abstract: There are many computer applications that can be made incremental. After a small perturbation to the computation at hand, intermediate values of a previous evaluation can be used to obtain the result of the new computation. This requires less time than reevaluating the entire computation. We propose the use of a directed graph to represent computations that we wish to make incremental. This graph, called a dependency graph, represents an intermediate computation at each vertex. Edges between vertices represent the dependence of intermediate computations on other intermediate computations. A change to the computation can be represented as a change in the dependency graph.

title: Attribute Grammars in Constraint-based Graphics Systems
abstract: A constraint-based graphics system provides a flexible, intuitive framework for describing relationships among graphical objects in applications such as document preparation, font design, and solid modelling. This paper describes two constraint-based graphics systems, micro-COSM and the IDEAL Synthesizer, and their implementation in terms of attribute grammars. The implementation of these two systems is noteworthy since they represent the first interactive constraint-based graphics systems that are implemented using attribute grammars. Our experiences with attribute grammars suggest that they provide a powerful framework for representing constraints and extracting important semantic information such as the equations to be solved by the constraint solver. We discuss the advantages of using attribute grammars in constraint-based graphics and from our experiences make several observations about the way attribute grammars should be used.

title: Is One NP Question as Powerful as Two?
abstract: For any integer k, $P^{SAT[k]}$ is the class of languages accepted by deterministic polynomial time oracle machines that make at most k queries to an oracle for SAT. It is easy to see that $P^{SAT[1]} \subseteq D^{P} \subseteq P^{SAT[2]}$. We use a technique called oracle replacement to show that if D^{P} = co-D^{P}, then there is a sparse set S such that $\overline{SAT} \in NP^{S}$, there exist "small" NP machines that recognize initial segments of $\overline{SAT}$, and the polynomial time hierarchy (PH) is contained in Δ^{3}_{P}. Thus for deterministic polynomial time oracle machines, if one NP question is as powerful as two, then the PH collapses to Δ^{3}_{P}. As another application of oracle replacement, we show that if there exists a sparse set $S \in NP^{SAT}$ such that $\overline{SAT} \in NP^{S}$, then $PH \subseteq \Delta^{3}_{P}$. We also discuss how oracle replacement is a unifying principle for many of the results concerning sparse oracles for NP.

title: An Environment for Formal Systems
abstract: This report describes the Environment for Formal Systems, EFS, that allows a user to interactively define the syntax and inference rules of a formal system and to construct proofs in the defined system. The EFS supports two AUTOMATH-like formalisms for encoding logics: the Edinburgh Logical Framework and the Calculus of Constructions. Facilities are provided for the definition of notational abbreviations and the construction of goal-directed proofs. New goal-directed rules can be interactively defined and checked for validity. The EFS was implemented with the Cornell Synthesizer Generator.

title: Computing a Trust Region Step for a Penalty Function
abstract: We consider the problem of minimizing a quadratic function subject to an ellipsoidal constraint when the matrix involved is the Hessian of a quadratic penalty function (i.e., a function of the form $p(x) = f(x) + \frac{1}{2\mu} c(x)^{T} c(x))$. Most applications of penalty functions require $p(x)$ to be minimized for values of μ decreasing to zero. In general, as μ tends to zero the nature of finite precision arithmetic causes a considerable loss of information about the null space of the constraint gradients when $\nabla^{2}p(x)$ is formed. This loss of information renders ordinary trust region Newton's methods unstable and degrades the accuracy of the solution to the trust region problem. The algorithm of More and Sorenson [1983] is modified so as to be more stable and less sensitive to the nature of finite precision arithmetic in this situation. Numerical experiments clearly demonstrate the stability of the proposed algorithm.

title: Verifying Temporal Properties without using Temporal Logic
abstract: An approach to proving temporal properties of concurrent programs that does not use temporal logic as an inference system is presented. The approach is based on using Buchi automata to specify properties. To show that a program satisfies a given property, proof obligations are derived from the Buchi automaton for that property. These obligations are discharged by devising suitable invariant assertions and variant functions for the program. The approach is shown to be sound and relatively complete. A mutual exclusion protocol illustrates its application.

title: Comparison of Two-Dimensional FFT Methods on the Hypercube : The Choice Between Strips and Patches
abstract: Complex two-dimensional FFT's up to size 256 X 256 points were implemented on the Intel iPSC/System 286 hypercube with emphasis on comparing the effects of data mapping, data transposition, and distributed FFT's. Comparison is based on partitioning the data into either strips or patches and three distinct methods are discussed. Of the two strips methods, the Transpose-Split implementation involves local independent FFT computations in both directions with an intervening transpose, while the Local-Distributed method performs local FFT's in one direction followed by distributed FFT's in the other. The patch or Block method partitions the matrix in submatrices and maps the (i,j)th block into node $i \hat j$ ($\hat$ denoting concatenation of binary numbers). Both the row-wise FFT's and the column-wise FFT's require inter-node communication for the distributed butterfly computations. Timing results show that on the Intel iPSC/System 286, there is hardly a difference between the three methods. This is due primarily to the inadequacies of Intel communication handling and its inability to overlap communication and computation as well as a lack of vector boards. A model follows where several important factors such as vectorization and communication complexity are considered. While timing results show that on a vectorized hypercube with ideal synchronization of communication and computation the Block method is asymptomatically the fastest. The conclusion is that this problem is highly system dependent and therefore no sweeping recommendations can be made.

title: On Parity and Near-Testability: $P^{A} \neq NT^{A}$ With Probability 1
abstract: The class of near-testable sets, NT, was defined by Goldsmith, Joseph, and Young. They noted that $P \subseteq NT \subseteq PSPACE$, and asked whether P=NT. This note shows that NT shares the same m-degree as the parity-based complexity class $\bigoplus P$ (i.e., $NT\equiv^{p}_{m} \oplus P$) and uses this to prove that relative to a random oracle $A, P^{A} \neq NT^{A}$ with probability one. Indeed, with probability one, $NT^{A} - (NP^{A} \bigcup coNP^{A}) \neq 0$.

title: A Paradigm for Concurrency Control Protocols for Distributed Databases
abstract: In this thesis, we present a paradigm for concurrency control protocols for distributed replicated databases. This paradigm presents a framework for both developing and analyzing concurrency control protocols, especially those that are designed to handle partitioning failures. Any concurrency control protocol that is an instance of the paradigm must be correct. We show that several known protocols are instances

of this paradigm. Consequently, these seemingly unrelated protocols can now be compared and their understanding is simplified. We also present two new concurrency control protocols: the virtual partitions protocol and the accessibility thresholds protocol. Both protocols allow the reading and writing of data in spite of site and communication failures, even when these failures lead to network partitioning. In neither protocol is it ever necessary for a read operation to physically access more than one copy, which makes these protocols desirable for applications where efficient read operations are necessary. The accessibility thresholds protocol provides the database designer with much flexibility in trading off the cost of executing operations and the availability of data objects. Unlike previous protocols, the cost of executing operations on an object is separated from the read and write availability of that object.

title: Partial Implementations in Program Derivation
abstract: A partial implementation of an abstract notation provides an implementation for some of the notations operations on some of the values in the notation. A collection of partial implementations of a fixed notation -differing in the selection of values and operations implemented- caters to different patterns of usage of the notation in individual programs. Partial implementations of a general mathematical notation are more appropriate to the formal development of programs than the more familiar paradigm of abstract data types with complete implementations. Furthermore, partial implementations provide the only realistic account of the implementation of finite machinery of many familiar mathematical notations. From a practical point of view, partial implementations of a fixed notation exhibit great reusability and provide a convenient approach to early prototyping in program development. The incorporation of mathematical notations into a programming system is studied, with particular regard to the formal development of programs in the style of Dijkstra and Gries. A new notion of encapsulation is presented to define partial implementations and a predicate-transformer characterization of implementation correctness is defined. The implementation correctness criterion simplifies and extends the original data-type implementation criterion of Hoare, generalizes implementation criterion for algebraic abstract data types, and accommodates the implementation of non-deterministic operations. Different variables of the same type may have different representations and implementations of operations within the same program. Not all implementations are adequate in a given program, so syntactic and semantic conditions are given to ensure that a proposed implementation of a variable is adequate.

title: Symmetry in Distributed Systems
abstract: A distributed computing system can be considered to be symmetric because of its topology or because of its behavior. Unfortunately, these different definitions can categorize the same system differently. The choice of definition becomes important when one is trying to prove that certain problems, such as the Dining Philosophers problem, cannot be solved on symmetric distributed computing systems. Since the behavioral definitions are based on the possible patterns of computation, it is much easier to use them for these proofs. However, behavioral definitions admit straightforward decision procedures. This thesis presents a new definition for symmetry, called similarity, that, while based on behavior of processes, is decidable given the initial configuration of the system. The decision procedure for similarity depends partly on the model of computation being used, but a way to discover these decision procedures is given

and is used to find decision procedures for a wide range of models of distributed computation. Distributed versions of these decision procedures form the basis of solutions to the problem of selecting a process as the leader. The thesis also shows how to use similarity to compare the relative power of different models of computation, including models with shared variables with and without locking, models using synchronous and asynchronous message-passing, models making different assumptions about fairness, and models based on probabilistic techniques.

title: Sparse Cholesky Factorization on a Multiprocessor
abstract: Systems of linear equations of the form $Ax = b,$ where A is a large sparse symmetric positive definite matrix, arise frequently in science and engineering. The sequential computation of the solution vector x is well understood and many algorithms for this problem employ the following steps. First, try to reorder the rows and columns of A so that its Cholesky factor L is sparse. Next, determine the structure of L by symbolically factoring A and allocate storage for L. Finally, numerically factor A and then compute x by solving the triangular systems $Ly=b$ and $L^{T}x=y$. In this thesis, we present parallel algorithms for the different steps of this computation. We design our algorithms for message-passing multiprocessors. The algorithms limit communication overhead and can solve problems that are too large to reside in the memory of any single processor. We provide numerical results based upon an implementation on an Intel hypercube. We begin by presenting a parallel column-oriented sparse numeric Cholesky factorization algorithm. Then, viewing A as a graph, we develop a parallel graph partitioning algorithm that we use to order the columns of A and partition them among the processors. In addition to producing a sparse L, the resulting ordering and partitioning allows for parallelism and reduces communication overhead during the remaining phases of the computation. The parallel graph partitioning algorithm is based on the sequential Kernighan-Lin algorithm for finding small edge separators. Since the computation of a particular column of L may depend on columns stored on several processors, the processors cannot operate independently. The elimination forest of A captures these dependencies and allows for efficient numeric factorization. We provide a parallel algorithm for computing the forest and prove its correctness. We also develop a parallel row-oriented symbolic factorization algorithm that uses the elimination forest. Finally, we describe fast parallel forward and backward triangular solve algorithms. These algorithms solve for the components of x requiring information from other processors by using a variant of Li and Coleman's dense triangular solve algorithms.

title: Maintaining Availability in Partitioned Replicated Databases
abstract: In a replicated database, a data item may have copies residing on several sites. A replica control protocol is necessary to ensure that data items with several copies behave as if they consist of a single copy, as far as users can tell. We describe a new replica control protocol that allows the accessing of data in spite of site failures and network partitioning. This protocol provides the database designer with a large degree of flexibility in deciding the degree of data availability, as well as the cost of accessing data.

title: Techniques for Simplifying the Programming of Distributed Systems
abstract: It is difficult to design and verify distributed programs that execute correctly despite transient processor failures, or despite variable and unpredictable processor speeds and message transmission times. In this thesis, we describe a checkpointing/rollback mechanism that allows programmers to write distributed programs with the simplifying assumption that processors do not fail, and then run these programs correctly on systems with transient processor failures. We also describe a translation mechanism that can be used to write programs with the simplifying assumptions that processors execute in synchronized steps and messages take exactly one step to arrive, and then run these programs correctly on systems that violate these assumptions. Both mechanisms are transparent to the programmer, and they can be applied to solve a large class of problems.

title: Understanding Protocols for Byzantine Clock Synchronization
abstract: All published fault-tolerant clock synchronization protocols are shown to result from refining a single paradigm. This allows the different clock synchronization protocols to be compared and permits presentation of a single correctness analysis that holds for all. The paradigm is based on a reliable time source that periodically causes events; detection of such an event causes a processor to reset its clock. In a distributed system, the reliable time source can be approximated by combining the values of processor clocks using a generalization of a "fault-tolerant average", called a convergence function. The performance of a clock synchronization protocol based on our paradigm can be quantified in terms of the two parameters that characterize the behavior of the convergence function used: accuracy and precision.

title: NC Algorithms for Computing the Number of Perfect Matchings in $K_{3,3}$-free Graphs and Related Problems
abstract: We show that the problem of computing the number of perfect matchings in $K_{3,3}$-free graphs is in NC. This stands in striking contrast with the #P-completeness of counting the number of perfect matchings in arbitrary graphs. As corollaries we obtain NC algorithms for checking if a given $K_{3,3}$-free graph has a perfect matching and if it has an EXACT MATCHING. Our result also opens up the possibility of obtaining an NC algorithm for finding a perfect matching in $K_{3,3}$-free graphs.

title: A Storage Efficient WY Representation for Products of Householder Transformations
abstract: A product $Q = P_{1} \cdots P_{r}$ of m-by-m Householder matrices can be written in the form $Q = I + WY^{T}$ where W and Y are each m-by-r. This is called the WY representation of Q. It is of interest when implementing Householder techniques in high-performance computing environments that "like" matrix-matrix multiplication. In this note we describe a storage efficient way to implement the WY representation. In particular, we show how the matrix Q can be expressed in the form $Q = I + YTY^{T}$ where $Y \epsilon R^{mxr}$ and $T \epsilon R^{rxr}$ with T upper triangular. Usually r less than less than m and so this "compact" WY representation requires less storage. When compared with the recent block-reflector strategy proposed by Schreiber and Parlett the new technique still has a storage advantage and involves a comparable amount of work.

title: A Non-Type-Theoretic Semantics For Type-Theoretic Language
abstract: Since 1970 several methods have been proposed for using formal systems of constructive logic as programming languages. One prominent approach is based upon systems of computationally significant terms

which either bear or are assigned types; these systems are essentially lambda calculi or combinatory logics in which either the terms are explicitly typed or else types are assigned to untyped terms in the manner of Curry. This thesis concerns two such systems, namely, Martin-Lof's intuitionistic type theory of 1979, and a variation of that theory upon which Nuprl is based. Nuprl is a system implemented at Cornell for developing functional programs and constructive proofs. The expressive machinery of these theories can be given a rather natural non-type-theoretic semantics that is not inherently constructive and yet closely follows the semantical explanation of type theory. The principal content of this thesis is a careful development of such a semantic reinterpretation with the intention of making the bulk of type-theoretic practice, of the kind arising from the use of Nuprl and formalizations of Martin-Lof's theory, independent of its original type-theoretic and constructive basis. The reinterpretation opens the type-theoretic methodology of programming to nonconstructivists and others who may not subscribe to the intuitionistic theory of types, preserving the features of type-theoretic language that make it a suitable language for programming. Moreover, the natural structural similarity between the type-theoretic concepts and their reinterpretations yields an analytic tool which may serve type-theorists as well. The body of this thesis has two phases. In the first, the semantic concepts of Martin-Lof's theory, including expressions, types, judgements of functionality, and universes, are reinterpreted. This phase culminates in a non-type-theoretic definition of the types explicitly defined in Martin-Lof's paper of 1979. The remainder of the thesis treats various topics of semantic significance, including the representation of propositions as types, the anticipation of new terms and types, certain "type-free" forms of inference, and a sort of "universe polymorphism." Finally, we shall reinterpret the semantics of Nuprl's judgements of functionality which differs radically from that of Martin-Lof's judgements in the use of assumptions.

title: Expressiveness Bounds for Completeness in Trace-Based Network Proof Systems
abstract: Network proof systems based on first-order specifications over channel traces are incomplete unless reasoning over the interleaving of communication events is permitted. Relatively complete trace-based proof systems using temporal logic have been described, but full temporal logic is more powerful than necessary. Using the interleaving approach, we isolate the expressiveness required of a relatively complete trace logic. A hierarchy of temporal logic subsets is then defined; a certain subset is shown to have necessary and sufficient expressive power for relative completeness.

title: Experiments in Automatic Phrase Indexing For Document Retrieval:A Comparison of Syntactic and Non-Syntactic Methods
abstract: In order for an automatic information retrieval system to effectively retrieve documents related to a given subject area, the content of each document in the system's database must be represented accurately. This study examines the hypothesis that better representations of document content can be constructed if the content analysis method takes into consideration the syntactic structure of document and query texts. Two methods of automatically generating phrases for use as content indicators have been implemented and tested experimentally. The non-syntactic (or statistical) method is based on simple text characteristics such as word frequency and the proximity of words in text. The syntactic method uses augmented phrase structure rules (production rules) to selectively extract phrases from parse trees generated by an automatic syntactic

analyzer. Experimental results show that the effect of non-syntactic phrase indexing is inconsistent. For the five collections tested, increases in average precision ranged from 22.7% to 2.2% over simple, single term indexing. The syntactic phrase indexing method was tested on two collections. Precision figures averaged over all test queries indicate that non-syntactic phrase indexing performs significantly better than syntactic phrase indexing for one collection, but that the difference is insignificant for the other collection. More detailed analysis of individual queries, however, indicates that the performance of both methods is highly variable, and that there is evidence that syntax-based indexing has certain benefits not available with the non-syntactic approach. Possible improvements of both methods of phrase indexing are considered. It is concluded that the prospects for improving the syntax-based approach to document indexing are better than for the non-syntactic approach. The PLNLP system was used for syntactic analysis of document and query texts, and for implementing the syntax-based phrase construction rules. The SMART information retrieval system was used for retrieval experimentation.

title: Computing the Singular Value Decomposition on a Distributed System of Vector Processors
abstract: Jacobi methods for computing the singular value decomposition (SVD) of a matrix are ideally suited for multiprocessor environments due to their inherent parallelism. In this paper we show how a block version of the two-sided Jacobi method can be used to compute the SVD efficiently on a distributed architecture. We compare two variants of this method that differ mainly in the degree to which they diagonalize a given subproblem. The first method is a true block generalization of the scalar scheme in that each off-diagonal block is completely annihilated. The second method is a scalar Jacobi algorithm reorganized in such a manner that it conforms to the block decomposition of the problem. We have performed experiments on the Loosely Coupled Array Processor (LCAP) system at IBM Kingston which for the purposes of this article can be viewed as a ring of up to ten FPS-164/MAX array processors. These experiments show that the block Jacobi algorithm performs well on a distributed system, especially when the processors have vector processing hardware. As an example, we were able to achieve a sustained performance of 159 MFlops on a 960-by-720 SVD problem using eight processors. A surprising outcome of these experiments is that the determining factor for the performance of the algorithm on a high-performance architecture is the subproblem solver, not the communication overhead of the algorithm.

title: Inductive Definition in Type Theory
abstract: Type theories can provide a foundational account of constructive mathematics, and for the computer scientist, they can also serve the dual roles of specification and programming languages. In the search for natural and expressive extensions to the NuPrl type theory, we are lead to consider forms of inductive and co-inductive definition. We realize these notions through the addition of two new type constructors, denoted $\mu and \nu$. This represents a step towards a more expressive theory, without adopting a completely impredicative notion of type. With these constructors we can define all the common inductive data types, from natural numbers to infinite trees. Through the propositions-as-types principle, these type constructors yield inductively defined propositions. The induction principle associated with the μ types lets us define well-founded recursive functions, and dual principle for the ν types lets us inductively define their "infinite" elements. We present another induction principle for the μ types which takes advantage of

the information hiding properties of the $\{ __ | __ \}$ type, and can be used to define an unbounded search operator, or more generally, to compute not with elements of the μ type, but under the assumption of its inhabitation. After presenting the proof rules for these new type constructors we give a semantic account, from which intuitionistic consistency is a consequence. First, we consider the the question of inductive types in the simpler setting of the second-order lambda calculus, where we prove a strong normalization property. We also consider typing terms in the presence of type constraints, and present a condition on the constraints (of polynomial complexity in the size of the constraints) for determining if the terms will be strongly normalizable or there will be a diverging typed term. Second, we develop a semantic account of the basic type theory, then relativize it to account for the impredicativity inherent in the definition of the new type constructors. We also show how this model can justify other impredicative type constructors, such as an impredicative type abstraction operation.

title: On the Semantics of "Data Type"
abstract: This paper considers the general problem of specifying the meaning of programming languages which include "data type definition facilities". The fundamental question posed in attempting to define such languages is: "what meaning should be given to a data type definition," or more simply, "what does data type mean?". In this paper we describe a new approach to defining the meaning of data types and give its application to the definition of a typed lambda calculus extension. We also prove a theorem stating that our language is "strongly typed".

title: Perfect Pipelining: A New Loop Parallelization Technique
abstract: Parallelizing compilers do not handle loops in a satisfactory manner. Fine-grain transformations capture irregular parallelism inside a loop body not amenable to coarser approaches but have limited ability to exploit parallelism across iterations. Coarser methods sacrifice irregular forms of parallelism in favor of pipelining (overlapping) iterations. In this paper we present a new transformation, Perfect Pipelining, that bridges the gap between these fine-and coarse-grain transformations while retaining the desirable features of both. This is accomplished even in the presence of conditional branches and resource constraints. For loops typically encountered in practice, Perfect Pipelining achieves the effect of full loop unrolling coupled with fine-grain parallelization. To make our claims rigorous, we develop a formalism for parallelization. The formalism can also be used to compare transformations across computational models. As an illustration, we show that Doacross, a transformation intended for synchronous and asynchronous multiprocessors, can be expressed as a restriction of Perfect Pipelining.

title: Lazy Evaluation and the Logic Variable
abstract: Functional languages can be enriched with logic variables to provide new computational features such as incremental construction of data structures. In this paper, we present a novel application for logic variables that highlights their importance: we argue that they are essential for efficient implementations of pure functional languages. This point is made by demonstrating that logic variables are required for explicating the process of demand propagation in lazy evaluation of functional programs. There are two applications of this result. For dataflow researchers, it offers a simple and efficient implementation of laziness on dataflow machines. For researchers investigating lazy graph reduction, it suggests new strictness analysis algorithms in which logic variables play an important role.

title: Towards Task Level Robot Programming
abstract: This paper summarizes our research efforts in robotics. The primary goal is to bring robotics science closer to its goal of task-level planning. We approach this goal through blend of theory, implementation, and experimentation. We have identified several key problem areas on which to concentrate, and are undertaking research on generating assembly strategies from task-level descriptions. Our projects focus on: Algorithmic

techniques for modelling geometric constraints, and the planning of robot motions using these constraints. The synthesis of compliant motion programs using the geometric constraints imposed by the task. The explicit modelling of uncertainty and error in sensing, control, and the shape of the manipulated parts. The development of a precise theory of Error Diagnosis and Recovery, and a method for generating sensor-based plans with built-in error detection and recovery. The heart of this research lies in a geometrical planning theory, for reasoning about and manipulating physical systems. We will develop this underlying theory, implement and test the theory in simulation, and conduct robotics laboratory experiments.

title: Simplified Voronoi Diagrams
abstract: We are interested in Voronoi diagrams as a tool in robot path planning, where the search for a path in an r dimensional space may be simplified to a search on an $r-1$ dimensional Voronoi diagram. We define a Voronoi diagram V based on a measure of distance which is not a true metric. This formulation has lower algebraic complexity than the usual definition, which is a considerable advantage in motion planning problems with many degrees of freedom. In its simplest form, the measure of distance between a point and a polytope is the maximum of the distances of the point from the half-spaces which pass through faces of the polytope. More generally, the measure is defined in configuration spaces which represent rotation. The Voronoi diagram defined using this distance measure is no longer a strong deformation retract of free space, but it has the following useful property: any path through free space which starts and ends on the diagram can be continuously deformed so that it lies entirely on the diagram. Thus it is still complete for motion planning, but it has lower algebraic complexity than a diagram based on the euclidean metric.

title: Planning Multi-Step Error Detection and Recovery Strategies
abstract: Robots must plan and execute tasks in the presence of uncertainty. Uncertainty arises from sensing errors, control errors, and uncertainty in the geometry of the environment. By employing a combined strategy of force and position control, a robot programmer can often guarantee reaching the desired final configuration from all the likely initial configurations. Such motion strategies permit robots to carry out tasks in the presence of significant uncertainty. However, compliant motion strategies are very difficult for humans to specify-for this reason we have been working on the automatic synthesis of motion strategies for robots. In previous work [D], we presented a framework for computing one-step motion strategies that are guaranteed to succeed in the presence of all three kinds of uncertainty. The motion strategies comprise sensor-based gross motions, compliant motions, and simple pushing motions. However, it is not always possible to find plans that are guaranteed to succeed. For example, if tolerancing errors render an assembly infeasible, the plan executor should stop and signal failure. In such cases the insistence on guaranteed success is too restrictive. For this reason we investigate Error Detection and Recovery (EDR) strategies. EDR plans will succeed or fail recognizably: in these more general strategies, there is no possibility that the plan will fail without the executor realizing it. The EDR framework fills a gap when guaranteed plans cannot be found or do not exist: it provides a technology for constructing plans that might work, but fail in a "reasonable" way when they cannot. We describe techniques for planning multi-step EDR strategies in the presence of uncertainty. Multi-step strategies are considerably more difficult to generate, and we introduce three approaches for their synthesis: these are the Push-forward Algorithm, Failure Mode Analysis, and

the Weak EDR Theory. We have implemented the theory in the form of a planner, called LIMITED, in the domain of planar assemblies.

title: Term Weighting Approaches in Automatic Text Retrieval
abstract: The experimental evidence accumulated over the past 20 years indicates that textindexing systems based on the assignment of appropriately weighted single terms produce retrieval results that are superior to those obtainable with other more elaborate text representations. These results depend crucially on the choice of effective term weighting systems. This paper summarizes the insights gained in automatic term weighting, and provides baseline single term indexing models with which other more elaborate content analysis procedures can be compared.

title: The Fast Fourier Transform on Hypercube Parallel Computers
abstract: The Fast Fourier Transform appears frequently in scientific computing. Therefore it is desirable to implement it efficiently on parallel computers. In this thesis, we investigate several different aspects of parallel Fast Fourier Transform implementation techniques for distributed-memory message-passing systems such as hypercube multiprocessors. We describe various Fast Fourier Transform algorithms using a matrix notation. An error analysis is presented that considers the effect of different methods used in the computation of the Fourier Transform coefficients as well as accumulated roundoff. New implementations of one and two-dimensional Fast Fourier Transforms are presented along with comparisons with existing methods. New algorithms for symmetric transforms are also developed and the results show excellent speedup when implemented on the Intel iPSC hypercube.

title: Computations, Residuals, and the Power of Indeterminacy
abstract: We investigate the power of Kahn-style dataflow networks, with processes that may exhibit indeterminate behavior. Our main result is a theorem about networks of "monotone" processes, which shows: (1) that the input/output relation of such a network is a total and monotone relation; and (2) every relation that is total, monotone, and continuous in a certain sense, is the input/output relation of such a network. Now, the class of monotone networks includes networks that compute arbitrary continuous input/output functions, an "angelic merge" network, and an "infinity-fair merge" network that exhibits countably indeterminate branching. Since the "fair merge" relation is neither monotone nor continuous, a corollary of our main result is the impossibility of implementing fair merge in terms of continuous functions, angelic merge, and infinity-fair merge. Our results are established by applying the powerful technique of "residuals" to the computations of a network. Residuals, which have previously been used to investigate optimal reduction strategies for the λ-calculus, have recently been demonstrated by one of the authors (Stark) also to be of use in reasoning about concurrent systems. Here, we define the general notion of a "residual operation" on an automaton, and show how residual operations defined on the components of a network induce a certain

preorder $\extend$ on the set of computations of the network. For networks of "monotone port automata," we show that the "fair" computations coincide with $\extend$-maximal computations. Our results follow from this extremely convenient property.

title: An Environment for Automated Reasoning About Partial Functions
abstract: We report on a new environment developed and implemented inside the Nuprl type theory that facilitates proving theorems about partial functions. It is the first such automated type-theoretic account of partiality. We demonstrate that such an environment can be used effectively for proving theorems about computability and for developing partial programs with correctness proofs. This extends the well-known proofs as programs paradigm to partial functions.

title: ROPE: A New Twist in Computer Architectures
abstract: Supercomputer architectures are not as fast as logic technology allows because memories are slow than the CPU, conditional jumps limit the usefulness of pipelining and prefetching mechanisms, and functional-unit parallelism is limited by the speed of hardware scheduling. We propose a supercomputer architecture called Ring Of Prefetch Elements (ROPE) that attempts to solve the problems of memory latency and conditional jumps without hardware scheduling. ROPE consists of a pipelined CPU or very-large-instruction-word data path with a new instruction prefetching mechanism that supports general multi-way conditional jumps. To get high-performance without scheduling hardware, ROPE relies on an optimizing compiler based on a global code transformation technique (Percolation Scheduling). This paper describes both the promise and the limitations of ROPE.

title: Supplying High Availability with a Standard Network File System
abstract: This paper describes the design of a network file service that is tolerant to fail-stop failures and can be run on top of a standard network file service. The fault-tolerance is completely transparent, so the resulting file system can support the same set of heterogeneous workstations and applications as the chosen standard supports. To demonstrate that our design can provide the benefit of highly available files at a reasonable cost to the user, we implemented a prototype based on the Sun NFS protocol. Our approach is not limited to being used with NFS, however. The methodology we used should apply to any network file service built along the client-server model.

title: The Complexity of Planar Compliant Motion Planning Under Uncertainty
abstract: We consider the computational complexity of planning compliant motions in the plane, given geometric bounds on the uncertainty in sensing and control. We can give efficient algorithms for generating and verifying compliant motion strategies that are guaranteed to succeed as long as the sensing and control uncertainties lie within the specified bounds. We also consider the case where a compliant motion plan is required to succeed over some parametric family of geometries. While these problems are known to be intractable in 3D, we identify tractable subclasses in the plane.

title: On the Expressive Power of Indeterminate Network Primitives
abstract: It is well known that a fair merge primitive leads to unbounded indeterminacy. In this paper we show that unbounded indeterminacy cannot express a fair merge in the setting of Kahn-style dataflow networks.

Intuitively, unbounded indeterminacy can be used to program a fair merge when it is guaranteed that data will always be available. But such schemes rely on predictive scheduling and they may fail if one of the inputs to the merge is a finite stream. It is reasonable to expect that if one were to add a primitive which "knows how to avoid bottom" (so called "angelic merge") then one could use this in conjunction with unbounded choice in order to produce a fair merge. Somewhat surprisingly, this expectation is incorrect as we show in this paper. The method we use to prove this is to identify a property which generalises monotonicity to indeterminate networks and then show that this property is possessed by determinate networks and by unbounded choice and by angelic merge but not by fair merge. It appears that there is a hierarchy of inequivalent indeterminate primitives all of which feature some form of unbounded indeterminacy.

title: Metamathematical Extensibility in Type Theory
abstract: An automated theorem prover is said to be metamathematically extensible if a metalanguage can be employed by the user to soundly extend the reasoning capabilities of the system. In this thesis, we present a framework for metamathematical extensibility for a system based upon a type-theoretic logic, the Nuprl system. Using this framework, the user can construct programs called proof tactics that may be used to provide new reasoning capabilities for the logic. These proof tactics can encode reasoning methods as simple asd a derived rule of inference or as ambitious as a theorem prover. The design of the framework ensures that all proof tactics are correct. A formal metalanguage called Metaprl is defined that represents the proof theory of Nuprl in a natural and computationally-oriented fashion. The logic of Metaprl is an extension of the constructive type theory of Nuprl. Type theories like Nuprl and Metaprl are distinguished by the uniform treatment of computations (programs) and logical propositions and by rich languages for expressing computations. In Metaprl, formal specifications for tactics may be written and formally correct tactics extracted from the proofs of the specification. Three classes of tactics are defined: complete tactics, partial tactics, and search tactics. Complete tactics are analogous to derived axioms for the Nuprl logic. Partial tactics are analogous to derived rules of inference. Search tactics are analogous to the procedural tactics of LCF and the current Nuprl system. Examples from each class of tactics are presented. There are a number of advantages to using a formal logic as a metalanguage for metamathematical extensibility. System-implemented reflection principles guarantee that the framework is a conservative extension of Nuprl. The expressiveness of the Metaprl logic allows the validity of tactics to be ensured. Often it is not even necessary to execute tactics since they have been proved correct and all that is required is that a proof exists; the exact form for the proof is not needed. This can result in substantial computational savings. Finally, the construction of a metalanguage for metamathematical extensibility for Nuprl is generalized to a hierarchy of metalanguages, each logic providing for metamathematical extensibility of the preceeding logic.

title: An Assertional Characterization of Serializability and Locking
abstract: The problem of synchronizing transactions in a database system so that concurrent execution transforms the system from one consistent state to another is called the Concurrency Control Problem. Over the past 20 years, a property of concurrent execution called serializability has evolved as a universal paradign for colving the Concurrency Control Problem. Up until now, most work on serializability has been characterized by an emphasis on sequences of operations. Researchers studying programming logics and methodologies have developed a different approach to characterizing the semantics of concurrent programs. This approach is called assertional reasoning, and emphasizes the system state instead of sequences of operations. This dissertation describes the extension of the formalisms and tools of assertional reasoning to the Concurrency Control Problem. Proposed is a definition of serializability that generalizes previous definitions in many respects. Two methods are described by which this definition of serializability can be specified in an assertional programming logic using formulas called proof outlines. As a consequence of specifying serializability with proof outlines, it becomes possible to formally verify serializability. The use of an assertional programming logic eliminates the need to explicitly consider transaction interleavings, simplifying verfication. Another consequence of specifying serializability with proof outlines is the ability to derive synchronization protocols for serializability. This possibility is realized in the form of a method for deriving locking protocols from assertional specifications. The method is based on a novel view of locking, in which locks held by transactions reflect properties of the system state. Using this method, semantic information available during the derivation process can be used to obtain locking protocols permiting greater concurrency among transactions than locking protocols obtained by more traditional methods. Examples are given throughout the dissertation to illustrate the methods described.

title: A Geometric Approach to Error Detection and Recovery for Robot Motion Planning With Uncertainty
abstract: Robots must plan and execute tasks in the presence of uncertainty. Uncertainty arises from sensing errors, control errors, and uncertainty in the geometric models of the environment and of the robot. The last, which we will call model uncertainty, has received little previous attention. In this paper we present a formal framework for computing motion strategies which are guaranteed to succeed in the presence of all three kinds of uncertainty. We show that it is effectively computable for some simple cases. The motion strategies we consider include sensor-based gross motions, compliant motions, and simple pushing motions. We show that model uncertainty can be represented by position uncertainty in a generalized configuration space. We describe the structure of this space, and how motion strategies may be planned in it. It is not always possible to find plans that are guaranteed to succeed. In the presence of model error, such plans may not even exist. For this reason we investigate Error Detection and Recovery (EDR) strategies. We characterize what such strategies are, and propose a formal framework for constructing them. Our theory represents what is perhaps the first systematic attack on the problem of error detection and recovery based on geometric and physical reasoning.

title: Static Analysis of Aliases and Side Effects in Higher-Order Languages
abstract: In recent years, there has been substantial interest in the development of programming languages for new parallel architectures. A basic design conflict arises because languages with simple semantics tend to use storage inefficiently, whereas languages allowing the programmer to access storage explicitly are difficult to analyze. We present a compile-time estimation scheme for determining whether an expression in an imperative language either uses or updates the store. We also determine the aliasing behavior of expressions and in general, we can tell whether the evaluation of two expressions interfere. Current interprocedural dataflow techniques for aliasing and side effect inference are valid for first-order languages. Our inference schemes provide information about aliasing and side effects in a higher-order expression language with call-by-value semantics. The higher order character of the language represents only a partial obstacle. On the other hand, the presence of l-valued expressions has the consequence that aliasing information must be computed for all expressions, and cannot be represented as a relation among identifiers. Furthermore, the introduction of pointers make aliasing and side effects flow-dependent properties. Abstract interpretation techniques allow us to define compositional static inference schemes for aliasing and side effects, which can be proved sound with respect to the standard semantics by structural induction. The abstract interpretation functions are easy to modify, in case a different type of information is requested. We also discuss how different language features may affect the static analyses, simplifying them or making them untractable. The abstract interpretation functions implicitly define static inference algorithms, which can easily be implemented by an attribute grammar, or any other tool capable of performing computations on the abstract syntax tree. The accuracy of these algorithms is better than for the dataflow ones, because we make use of control flow information. Our algorithms also compare favorably in complexity, but the dataflow approach is probably cheaper in most practical settings. In addition, our schemes can give information even in the presence of dynamically allocated data structures.

title: Computational Metatheory in Nuprl
abstract: This paper describes an implementation within Nuprl of mechanisms that support the use of Nuprl's type theory as a language for constructing theorem-provind procedures. The main componenet of the implementation is a large library of definitions, theorems and proofs. This library may be regarded as the beginning of a book of formal mathematics; it contains the formal development and explanation of a useful subset of Nuprl's metatheory, and of a mechanism for translating results established about this embedded metatheory to the object level. Nuprl's rich type theory, besides permitting the internal development of this partial reflection mechanism, allows us to make abstractions that drastically reduce the burden of establishing the correctness of new theorem-proving procedures. Our library includes a formally verified term-rewriting system.

title: Restricted Turing Reducibilities and the Structure of the Polynomial Time Hierarchy
abstract: The polynomialtime many-one and Turing reducibilities, Karp and Cook reducibilities respectively, play an major role in computational complexity theory, particularly in the study of such classes as P, NP, the polynomial time hierarchy (PH), and PSPACE. In this thesis, we consider polynomial time Turing reducibilities with various restricted oracle access mechanisms such as restrictions on the number of queries allowed or requiring that all queries be made at once, in parallel. Such restrictions are related to polynomial time truth-table and bounded truth-table reducibilities. We focus mostly on classes of languages reducible to NP sets via these reducibilities. For any integer $k, P^{NP[k]}$ is the class of languages recognizable in polynomial time with k queries to an oracle from NP. The query hierarchy, QH, is $\bigcup_{k} P^{NP[k]}$. The class $P^{NP[\log n]}$ is the set of languages recognizable with $O(\log n)$ queries. Two related hierarchies are the Boolean hierarchy Boolean hierarchy (BH) and the parallel query hierarchy $(\rm QH_{||})$. The BH, QH, and $\rm QH_{||}$ intertwine to form a rich structure within P^{NP}: NP $\cup$ co-NP $\subseteq P^{NP[1]} \subseteq P^{NP[2]} \subseteq \cdots \subseteq QH = QH_{||} = BH \subseteq P^{NP[\log n]} \subseteq P^{NP}.$ We show that the structure of these classes is closely tied to the existence of nonuniform algorithms for NP and co-NP languages and to the structure of the PH as a whole. We improve Mahaney's result for sparse Turing-complete sets for NP by showing that if there exists a sparse set $S \in NP$ such that co-NP $\subseteq NP^{S}$, then PH $\subseteq P^{NP[\log n]}$. We show that there are relativized worlds where this collapse is optimal, and thus we provide a clear distinction between the effects of a sparse many-one-complete set and a sparse Turing-complete set for NP. We prove that if the BH, QH, or $QH_{||}$ collapses, for instance, if $D^{P} =$co-D^{P} or if $P^{NP[k]} = P^{NP[k+1]}$, then there exists a sparse set S such that co-NP $\subseteq NP^{S}, and therefore the PH collapses to $P^{NP^{NP}[\log n]}$, a subclass of the Δ^{P}_{3} level of the PH. Hence the structure of unsatisfiable Boolean formulas, co-NP, and the whole PH are all closely related to the structure of the BH and to the issue of how deterministic polynomial time algorithms can access the information from NP oracles.

title: A Formal Account of Notational Definition
abstract: In the course of developing a mathematical theory or proof it is a common practice to introduce

new notation to represent notation that is previously understood. This paper presents a formal account that is intended to model the practice of introducing and using notational (abbreviative) definitions. The aim of this work is a pragmatic one: to provide a framework useful in the design and implementation of secure proof system interfaces which accommodate, as much as possible, conventional mathematical practice. A typed λ-calculus is used to represent expressions of a given object language. A new type of equation, called a Δ-equation, is introduced to model conventional definitional equations.

title: Computational Foundations of Basic Recursive Function Theory
abstract: The theory of computability, or basic recursive function theory as it is often called, is usually motivated and developed using Church's Thesis. Here we show that there is an alternative computability theory in which some of the basic results on unsolvability become more absolute, results on completeness become simpler, and many of the central concepts become more abstract. In this approach computations are viewed as mathematical objects, and the major theorems in recursion theory may be classified according to which axioms about computation are needed to prove them. The theory is a typed theory of functions over the natural numbers, and there are unsolvable problems in this setting independent of the existence of indexings. The unsolvability results are interpreted to show that the partial function concept, so important in computer science, serves to distinguish between classical and constructive type theories (in a different way than does the decidability concept as expressed in the law of excluded middle). The implications of these ideas for the logical foundations of computer science are discussed, particularly in the context of recent interest in using constructive type theory in programming.

title: Optimal Loop Parallelization

abstract: Parallelizing compilers promise to exploit the parallelism available in a given program, particularly parallelism that is too low-level or irregular to be expressed by hand in an algorithm. However, existing parallelization techniques do not handle loops in a satisfactory manner. Fine-grain (instruction level) parallelization, or compaction, captures irregular parallelism inside a loop body but does not exploit parallelism across loop iterations. Coarser methods, such as doacross [9], sacrifice irregular forms of parallelism in favor of pipelining iterations (software pipelining). Both of these approaches often yield suboptimal speedups even under the best conditions-when resources are plentiful and processors are synchronous. In this paper we present a new technique bridging the gap between fine-and coarse-grain loop parallelization, allowing the exploitation of parallelism inside and across loop iterations. Furthermore, we show that, given a loop and a set of dependencies between its statements, the execution schedule obtained by our transformation is time optimal: no transformation of the loop based on the given data-dependencies can yield a shorter running time for that loop.

title: An Incremental Planning Algorithm for Ordering Equations in a Multilinear System of Constraints
abstract: Constraint equations are increasingly being used in interactive applications such as graphics, logical programming, and simulation that demand immediate feedback. To handle the performance requirements imposed by such systems constraint evaluators must use incremental satisfaction techniques. In this paper, we apply these techniques to noncircular, multilinear systems of equations. The constraint satisfaction process is divided into two phases--a planning phase that imposes a topological order on the equations and an execution phase that evaluates the equations. A planning algorithm is presented that incrementally updates this order each time the constraint system changes. This technique achieves significant performance improvements in large constraint systems since modifications generally perturb only a small portion of the topological order.

title: McCarthy's Amb Cannot Implement Fair Merge
abstract: In this paper, we establish that fair merge is a powerful non-deterministic primitive that cannot be implemented in terms of other well-known primitives. It is well known that fair merge embodies countable

non-determinism. It is also been known that McCarthy's amb embodies countable non-determinism. It had not been known, however, whether amb could implement a fair merge. We show that countable non-determinism together with angelic non-determinism cannot implement fair merge even in dynamic dataflow networks. This settles a question posed by Abramsky over four years ago. Earlier work had suggested this result by showing that for static dataflow networks, one cannot implement fair merge using angelic merge.

title: On Time Versus Space
abstract: It is shown that every deterministic multitape Turing machine of time complexity t(n)/log t(n). Consequently, for tape constructable t(n), the class of languages recognizable by multitape Turing machines of time complexity t(n) is strictly contained in the class of languages recognized by Turing machines of tape complexity t(n). In particular, the context sensitive languages can not be recognized in linear time by deterministic multitape Turing machines. Keywords and phrases: Turing machines, time complexity, tape complexity.

title: A Round-Robin Parallel Partitioning Algorithm
abstract: We develop parallel heuristic algorithms for partitioning the vertices of a graph into many groups of roughly equal size so that few edges connect vertices in different groups. The algorithms are intended for a message passing multiprocessor such as a hypercube, but only require the processors to be connected as a ring. They are based on the Kernighan-Lin algorithm, which finds a small edge separator that divides a graph into two pieces of equal size. Each of the algorithms features a parameter that allows for a trade-off between the potentially conflicting goals of reducing the number of edges between different groups and keeping the sizes of the groups roughly the same. These algorithms are applied to the problem of parallel block oriented Cholesky factorization. For an efficient factorization, we need a graph partition in which few pairs of vertex groups are interconnected; that is, we desire the quotient graph induced by the partition to be sparse. We discuss how standard partitioning heuristics may fail to give sparse quotient graphs and how they can be modified to correct this.

title: A Temporal-Logic Based Compositional Proof System for Real-Time Message Passing
abstract: We consider a model of real-time network computation in which synchronous communication events occur during (possibly overlapping) intervals along a dense time scale. A specification language for processes and networks based on real-time temporal logic is defined. We give a simple proof system for network specifications when specifications for component processes are given. The proof system is then extended for a version of real-time CSP, under the assumption that all communications take some fixed length of time. Finally, it is shown that this proof system can be modified to allow varying communication lengths. All versions of the proof system are compositional, sound, and relatively complete.

title: Compaction-Based Parallelization
abstract: We present a transformational system for extracting parallelism from programs. Our transformations generate code for synchronous parallel computers, such as Very Long Instruction Word and pipelined

machines. The transformational system, which is based on percolation scheduling,is simple and uniform. There are four primitive transformations-three that perform code motion plus loop unrolling-from which all parallelizing algorithms are constructed. Our transformations are studied as a formal system. We define a formal measure of program improvement, and show that our transformations improve programs with respect to the measure. This formal approach allows a number of results on the expressive power of our transformations. Most importantly, we show that it is possible to compute limits of infinite sequences of the primitive transformations. This leads to a number of new algorithms for software pipelining, including: an algorithm that generates optimal code for loops without tests, an algorithm for software pipelining of multiple nested loops, and a general solution to the problem of software pipelining in the presence of tests. Using the four primitives and the limit-taking transformation, it is possible to express the classical parallelization techniques for vector, multiprocessor, and VLIW machines, such as doacross, the wavefront method, loop interchange, trace scheduling, and a simple form of vectorization. Thus, our transformational system can be viewed as a formal foundation for the area of parallelization.

title: Solution of Nonlinear Least-Square Problems on a Multiprocessor
abstract: In this paper we describe algorithms for solving nonlinear least-squares problems on a message-passing multiprocessor. We demonstrate new parallel algorithms, including an efficient parallel algorithm for determining the Levenberg-Marquardt parameter and a new row-oriented QR factorization algorithm. Experimental results obtained on an Intel iPSC hypercube are presented and compared with sequential MINPACK code executed on a single processor. These experimental results show that essentially full efficiency is obtained for problems where the row size is sufficiently larger than the number of processors. These algorithms have the advantage of involving only simple data movements and consequently are not constrained to the hypercube architecture.

title: Recursive Data Structures and Parallelism Detection
abstract: Interference estimation is a key aspect of automatic parallelization of programs. In this paper we study the problem of estimating interference in a language with dynamic data-structures. We focus on the case of binary trees to illustrate the approach. We develop a structural flow-analysis technique that allows us to estimate whether two statements influence disjoint sub-trees of a forest of dynamically-allocated binary trees. The method uses a regular-expression-like representation of the relationships between the nodes of the trees and is based on the algebraic properties of such expressions. We have implemented our analysis in Standard ML and have obtained some promising experimental results.

title: Automating Reasoning in an Implementation of Constructive Type Theory
abstract: The starting point for this thesis is the Nuprl proof development system. Nuprl is an environment for the development of formal computational mathematics and has a rich constructive type theory as a logical

basis. It provides sophisticated editors and an integrated tactic mechanism that allows the programming of guaranteed-sound extensions to the inference system. The work presented in this thesis concerns the automation of reasoning in Nuprl, and consists of three parts. The first is a collection of general-purpose tactics. These tactics are simple enough that their function can be readily understood, yet powerful enough to support development of substantial formal mathematics. The second part is the use of Nuprl to solve an open problem in the theory of programming languages. The set of basic tactics together with various tools provided by Nuprl play a crucial role in the solution, and it seems that this problem is not tractable without computer assistance. The third part is an implementation within Nuprl of mechanisms that support the use of Nuprl's type theory as a language for constructing theorem-proving procedures. The main component of the implementation is a large library of definitions, theorems and proofs. This library may be regarded as the beginning of a book of formal mathematics; it contains a complete formal development and explanation of a useful subset of Nuprl's metatheory, and of a mechanism for translating results established about this embedded metatheory to the object level. The type theory, besides permitting the internal development of this partial reflection mechanism, allows us to make abstractions that drastically reduce the burden of establishing the correctness of new theorem-proving procedures. Our library includes a formally verified term-rewriting system.

title: A Direct Active Set Algorithm for Large Sparse Quadratic Programs withSimple Bounds
abstract: We show how a direct active set method for solving definite and indefinite quadratic programs with simple bounds can be efficiently implemented for large sparse problems. All of the necessary factorizations can be carried out in a static data structure that is set up before the numeric computation begins. The space required for these factorizations is no larger than that required for a single sparse Cholesky factorization of a matrix with the same sparsity structure as the Hessian of the quadratic. We propose several improvements to this basic algorithm: a new way to find a search direction in the indefinite case that allows us to free more than one variable at a time and a new heuristic method for finding a starting point. These ideas are motivated by the two-norm trust region problem. Additionally, we also show how projection techniques can be used to add several constraints to the active set at each iteration. Our experimental results show that an algorithm with these improvements runs much faster than the basic algorithm for positive definite problems and finds local minima with lower function values for indefinite problems.

title: Parallel Algorithms For Maximum Matching And Other Problems On Interval Graphs
abstract: In this paper, we consider parallel algorithms on interval graphs. An interval graph is a graph having a one-to-one correspondence with a sequence of intervals on the real line, such that each vertex maps to an interval in the sequence and an edge exists between two vertices if and only if the corresponding intervals overlap. Throughout the paper we use the CREW PRAM model. Our main result is an $O(\log^{2} n)$ time, $O(n^{6}/\log n)$ processor algorithm for maximum matching on interval graphs. We give PT-optimal algorithms for maximum weighted clique, maximum independent set, minimum clique cover, and minimum dominating set for representations of interval graphs; and Hamiltonian circuit for representations of proper interval graphs. We also give an improved algorithm for minimum bandwidth on representations of proper interval graphs. In addition, we present $O (\log n)$ time, $O (n^{2}/\log n)$ processor algorithms

for depth-first search on representations of interval graphs and maximum matching on representations of proper interval graphs.

title: The Use of Efficient Broadcast Protocols in Asynchronous Distributed Systems
abstract: Reliable broadcast protocols are important tools in distributed and fault-tolerant programming. They are useful for sharing information and for maintaining replicated data in a distributed system. However, a wide range of such protocols has been proposed. These protocols differ in their fault tolerance and delivery ordering characteristics. There is a tradeoff between the cost of a broadcast protocol and how much ordering it provides. It is, therefore, desirable to employ protocols that support only a low degree of ordering whenever possible. This dissertation presents techniques for deciding how strongly ordered a protocol is necessary to solve a given application problem. We show that there are two distinct classes of application problems: problems that can be solved with efficient, asynchronous protocols, and problems that require global ordering. We introduce the concept of a linearization function that maps partially ordered sets of events to totally ordered histories. We show how to construct an asynchronous implementation that solves a given problem if a linearization function for it can be found. We prove that in general the question of whether a problem has an asynchronous solution is undecidable. Hence there exists no general algorithm that would automatically construct a suitable linearization function for a given problem. Therefore, we consider an important subclass of problems that have certain commutativity properties. We present techniques for constructing asynchronous implementations for this class. These techniques are useful for constructing efficient asynchronous implementations for a broad range of practical problems.

title: On the Complexity of Kinodynamic Planning
abstract: In robotics, kinodynamic planning attempts to solve a motion problem subject to simultaneous kinematic and dynamic constraints. We consider the following problem: given a robot system, find a minimal-time trajectory from a start position and velocity to a goal position and velocity, while avoiding obstacles and respecting dynamic constraints on velocity and acceleration. We consider the simplified case of a point mass under Newtonian mechanics, together with velocity and acceleration bounds. The point must be flown from a start to a goal, amidst polyhedral obstacles in 2D or 3D. While exact solutions to this problem are not known, we provide the first provably good approximation algorithm, and show that it runs in polynomial time.

title: Building Theories in Nuprl
abstract: This paper provides an account of how mathematical knowledge is represented, reasoned about, and used computationally in a mechanized constructive theorem proving environment. We accomplish this by presenting a particular theory developed in the Nuprl proof development system: finite set theory culminating in Ramsey's theorem. We believe that this development is interesting as a case study in the relationship between constructive mathematics and computer science. Moreover, the aspects we emphasize-the high-level development of definitions and lemmas, the use of tactics to automate reasoning, and the use of type theory as a programming logic-are not restricted in relevance to this particular theory, and indicate the promise of our approach for other branches of constructive mathematics.

title: Techniques for Simplifying the Design of Distributed Systems
abstract: Distributed computing systems offer a number of advantages over centralized systems, such as the replication of data and functionality, which may result in increased performance and fault-tolerance. The design of protocols for distributed systems is more complex than for centralized systems because coordination and cooperation between the different processors can be difficult to achieve. Among the factors complicating this design are the following: lack of processor synchronization, lack of common knowledge, and processor failures. This thesis presents techniques for simplifying the design of distributed systems by addressing these three complicating factors. Processor synchronization is provided by using logical clocks as if they are real-time (and hence, perfectly synchronized) clocks. This can be done in solutions to a large class of problems. Common knowledge is simulated by timestamped common knowledge, which is identical to true common knowledge in systems with perfectly synchronized clocks. A communication primitive, called publication, is defined which achieves timestamped common knowledge, and an implementation of publications is given that uses logical clocks. When solving problems in the class characterized earlier, publications can be used as if they achieve true common knowledge. The design of fault-tolerant protocols is simplified through methods that automatically translate protocols tolerant of benign failures into ones tolerant of more severe failures. The design task is reduced to that of designing simpler protocols.

title: Fine-Grain Compilation for Pipelined Machines
abstract: Computer architecture design requires careful attention to the balance between the complexity of code scheduling problems and the cost and feasibility of building a machine. In this paper, we show that recently developed software pipelining algorithms produce optimal or near-optimal code for a large class of loops when the target architecture is a clean pipelined parallel machine. The important feature of these machines is the absence of structural hazards. We argue that the robustness of the scheduling algorithms and relatively simple hardware make these machines realistic and cost-effective. To illustrate the delicate balance between architecture and scheduling complexity, we show that scheduling with structural hazards is NP-hard, and that there are machines with simple structural hazards for which vectorization and the software pipelining techniques generate poor code.

title: Incremental Computation and the Incremental Evaluation of Functional Programs
abstract: Incremental computation is generally thought of as the technique of efficiently updating the result of a computation when the input is changed. This idea is used in doing semantic checking in programming environments, document formatting in WYSIWYG editors and other applications. More generally, incremental computation is the technique of efficiently applying a function to a series of similar inputs. Much of the previous work on incremental computation has centered on incremental attribute grammar and incremental dependency graph evaluation schemes, but these techniques are only suitable for certain applications. This thesis examines an alternative method for providing incremental computation. Our results provide practical methods that can be used for applications such as theorem provers for which attribute grammars are unusable. Even for those problems for which attribute grammars are best suited, our methods perform almost as well as attribute grammars. We describe an incremental evaluator for functional programs that makes use of function caching. Function caching, or memoising, allows reuse of solutions to problems that were solved previously. We examine how function caching can be effectively used when solving problems that are similar to problems that were solved previously. In order for function caching to provide incremental evaluation, two similar problems must be solved by decomposing them into sub-problems in such a way that they share many common sub-problems. We formalize and quantify this idea with the notion of a stable decomposition, and we present data structures for representing sets and sequences that have stable decompositions. We solve several problems related to the efficient implementation of function caching. To perform function caching efficiently, one must be able to determine if two values are equal in constant time and perform updates applicatively. The data structures we present for sets and sequences

support these features. This was previously an open problem for representations that also supported efficient updates. We also examine how to calculate hash keys and perform fast equality tests for S-expressions and how to determine what to purge from a function cache when it is full. We report benchmarks that show our function caching implementation produces significant speed-ups in complex programs such as incremental theorem provers.

title: Notational Definition and Top-Down Refinement for Interactive Proof Development Systems
abstract: This thesis is concerned with issues related to the design and implementation of systems that support interactive proof development. The goal is to provide logic-independent frameworks that can be used in the design and implementation of component parts for such systems. In particular, this thesis will focus on two frameworks: a language-independent account of notational definition and a logic-independent account of a structure-oriented approach to the interactive construction of goal-directed proofs. These particular concerns were inspired and motivated by the Nuprl proof development system. However, the results presented in this thesis are meant to be applicable to a wide class of logics. The formal account of notational definition begins with the presentation of a simply typed λ-calculus together with a method of representing expressions in a given language $\cal L$ as λ-expressions. The λ-calculus has a very simple abbreviative mechanism that allows a new constant, introduced by means of a δ-equation, to represent a closed expression. A new construct, called a Δ-equation, is introduced. It provides a higher-level means of introducing new notations that is close to the conventional style of definition. A Δ-equation is given meaning by a translation into a simple δ-equation. The implementation of mechanisms that support notational definitions in interactive proof development systems as well as applications to Nuprl are discussed. The second part of the thesis presents a logic-independent framework for top-down proof development called abstract refinement. Rather than presenting, as is done for Nuprl, refinement and refinement rules as primitive notions that are extended by grafting on tactics, tactics are instead viewed as the basic notion from which refinement trees arise as tree-structured representations of the iterated composition of tactics. This is accomplished with the definition of a new construct called a tactic tree that extends the LCF tactics framework in a natural way. Several examples of proof development using tactic trees are presented. One example demonstrates that the refinement rules and the extraction mechanism of Nuprl can be modeled in this framework.

title: Partial Objects in Type Theory
abstract: Intuitionistic type theories, originally developed by Martin-Lof, provide a foundation for intuitionistic mathematics, much as set theory provides a foundation for mathematics. They are of interest to computer scientists because the objects typed are computations, making type theory an appropriate setting for reasoning about computation. Type theories such as Nuprl or the theories of Martin-Lof have types for objects that always terminate, but objects which may diverge are not directly typable. If type theory is to be a full-fledged theory for reasoning about computations, we need to be able to reason about potentially diverging objects. In this thesis we show how potentially diverging computations, which we call partial objects, may be typed by extending type theory to partial object type theory. New partial types are added to type partial objects. These types are usable: partial objects written in natural program notation can easily be

shown to lie in the types. In addition to being able to express partial objects, it is also important to be able to reason about them; for this purpose general principles are given for proving facts about partial objects via induction. The resulting theory serves as a foundation for computational as well as mathematical reasoning. It also gives insights into abstract recursion theory, leads to a new method for constructive reasoning, and sheds light on inductive methods for reasoning about recursive computation.

title: QR Factorization Algorithms for Coarse-Grained Distributed Systems
abstract: We present the techniques of adaptive blocking and incremental condition estimation which we believe to be useful for the computation of common matrix decompositions in high-performance environments. We apply these new techniques to algorithms for computing the Householder QR factorization with and without pivoting on a coarse-grained distributed system. For reasons of portability, we use a pipelined scheme on a ring of processors as the basis of our algorithms. To take advantage of possible floating point hardware on each node we develop a blocked version of the pipelined Householder QR algorithm that employs the compact WY representation for products of Householder matrices. While a strategy involving blocks of fixed width leads to increased floating point utilization per node, it also leads to increased load imbalance. To reconcile this tradeoff we introduce a variable width block strategy based on a model of the critical path of the algorithm. The resulting adaptive blocking strategy provides for good floating point performance per node while maintaining overall load balance. Experimental results on the Intel iPSC hypercube show that the adaptive blocking strategy performs indeed better than any fixed width blocking strategy. In the second part of our thesis we develop methods for introducing pivoting into the distributed QR factorization algorithm. Incorporating the traditional column pivoting strategy in a straightforward manner introduces a global synchronization constraint which results in increased communication overhead. A strictly local pivoting scheme avoids the resulting loss in efficiency, but has to be monitored for reliability. To this end, we introduce an incremental condition estimator which allows us to update the estimate of the smallest singular value of an upper triangular matrix R as new columns are added to R. The update requires only $O(n)$ flops an the storage of $O(n)$ words between successive steps. Experiments indicate that the incremental condition estimator is reliable despite its small computational cost. Using the incremental condition estimator we are then able to guard against the selection of troublesome pivot columns in our local pivoting scheme at little extra cost. Simulation results show that the resulting algorithm is about as reliable as the traditional QR factorization algorithm with column pivoting.

title: Parallel Sparse Cholesky Factorization
abstract: As sequential computers seem to be approaching their limits in CPU speed there is increasing interest in parallel computers. This development calls for parallel algorithms for problems that may already have efficient sequential algorithms. The problem of solving a linear system of equations arises in many areas of science and engineering. Quite often each equation only involves a small number of the variables. In that case the linear systems is sparse. If we can take advantage of the sparsity we can solve much larger systems. Consider the linear system $Ax = b$, where A is a sparse symmetric positive define matrix. A common approach to solving this system is to use Cholesky factorization. Algorithms that solve sparse linear systems using the Cholesky factorization usually consist of the following steps. First the matrix A

is permuted in order to get a sparse Cholesky factor L. Then there is the symbolic factorization of A to determine the nonzero structure of L. Finally the value of L is calculated in the numeric factorization phase and x is computed by solving the triangular systems $Ly = b$ and $L^{T}x = y$. In this thesis we present parallel algorithms for all the above steps except for the permutation step. Before the symbolic factorization we compute the elimination tree of A. Elimination trees have many applications in sparse matrix computations. Therefore our parallel algorithm to find elimination trees is important in its own right. The algorithm we present for symbolic factorization then uses the elimination tree to compute the nonzero structure of L. We next present a parallel algorithm to compute the numeric factorization of A. It runs in time proportional to the height of A's elimination tree times a log factor. We also show how that algorithm can be converted into an NC algorithm (i.d., an algorithm that runs in polygarithmic time) by use of fast algorithms for dense matrices. Finally we demonstrate a parallel algorithm to solve sparse triangular systems of equations. There again we show a version that runs in time related to the height of the elimination tree and a version that is an NC algorithm.

title: Incremental Constraint Satisfaction and its Application to Graphical Interfaces
abstract: Software that emphasizes pictures, rather than text, has become increasingly popular since the introduction of the Macintosh computer. Creating this software is a time-consuming task that can take months or years. Researchers have attempted to speed up this process by developing constraint-based tools that automate portions of the software development cycle. However, these tools are often limited in the types of applications they can generate, since 1) they lack powerful editing models that can manipulate complex data structures, such as lists, trees, and sets; and 2) in large applications, they cannot perform constraint satisfaction quickly enough to provide instantaneous feedback to the user. We present tools for overcoming each of these difficulties. First, we describe a new model, called constraint grammars, that integrates aspects of both attribute grammars and constraint-based, object systems to produce a powerful specification language for graphical interfaces. Constraint grammars integrate important concepts such as the part-whole hierarchy, almost-hierarchical structures, and multidirectional constraints. These features are augmented with a pattern-matching editing model that permits a designer to manipulate complex data structures. We then present techniques for incrementally resatisfying multidirectional, noncircular sets of constraints. It is shown that minimizing the number of re-solved constraints is NP-complete. We therefore describe an approach that attempts to minimize the amount of time spent updating the constraint solution. This technique divides constraint solving into two phases-a planning phase that linearly orders the constraints and an evaluation phase that solves the constraints using this linear order. Previous approaches have thrown away the linear order whenever the constraint system changes. However, this is unnecessary since only a local portion of the linear order is typically modified. We exploit this fact to develop an algorithm that incrementally updates this order. We the augment this algorithm with a heuristic that attempts to choose a linear order that minimizes the number of equations that the evaluation stage must solve. We present benchmarks that show that these algorithms can significantly reduce the number of equations examined by the planning phase and the number of equations solved by the evaluation phase.

title: Fast Polar Decomposition of an Arbitrary Matrix

abstract: The polar decomposition of an $m x n$ matrix A of full rank, where $m \geq n$, can be computed using a quadratically convergent algorithm of Higham [SIAM J. Sci. Stat. Comput., 7 (1986), pp.1160-1174]. The algorithm is based on a Newton iteration involving a matrix inverse. We show how with the use of a preliminary complete orthogonal decomposition the algorithm can be extended to arbitrary A. We also describe how to use the algorithm to compute the positive semi-definite square root of a Hermitian positive semi-definite matrix. We formulate a hybrid algorithm which adaptively switches from the matrix inversion based iteration to a matrix multiplication based iteration due to Kovarik, and to Bjorck and Bowie. The decision when to switch is made using a condition estimator. This "matrix multiplication rich" algorithm is shown to be more efficient on machines for which matrix multiplication can be executed 1.5 times faster than matrix inversion.

title: Generic Singularities of Robot Manipulators
abstract: The singularities of the differential kinematic map, i.e., of the manipulator Jacobian, are considered. We first examine the notion of a "generic" kinematic map, whose singularities form smooth manifolds of prescribed dimension in the joint space of the manipulator. For 3-joint robots, an equivalent condition for genericity using determinants is derived. The condition lends itself to symbolic computation and is sufficient for the study of decoupled manipulators, i.e., manipulators which can be separated into a 3-joint translating part and a 3-joint orienting part. The results are illustrated by analyzing the singularities of two classes of 3-joint positioning robots.

title: On the Structure of Bounded Queries to Arbitrary NP Sets
abstract: In [Kad87b], Kadin showed that if the Polynomial Hierarchy (PH) has infinitely many levels, then for all k, $P^{SAT[k]} \subseteq P^{SAT[k+1]}$. In this paper, we extend Kadin's technique to show that a proper query hierarchy is not an exclusive property of SAT. In fact, for any $A \in NP - \overbrace{low_{3}}$, if PH is infinite, then $P^{A[k]} \subseteq P^{A[k+1]}$. Moreover, for the case of parallel queries, we show that $P^{A||[k+1]}$ is not contained in $P^{SAT||[k]}$. We claim that having a proper query hierarchy is a consequence of the oracle access mechanism and not a result of the "hardness" of a set. To support this claim, we show that assuming PH is infinite, one can construct an intermediate set $B \in NP$ so that $P^{B[k+1]} \subseteq P^{SAT[k]}$. That is, the query hierarchy for B grows as "tall" as the query hierarchy for SAT. In addition, B is intermediate, so it is not "hard" in any sense (e.g., not NP hard under many-one, Turing, or strong nondeterministic reductions). Using these same techniques, we explore some other questions about query hierarchies. For example, we show that is there exists any A such that $P^{A[2]} = P^{SAT[1]}$ then PH collapses to Δ^{P}_{3}.

title: Providing Design Abstractions in Distributed Systems
abstract: The design of protocols for distributed systems is more complex than for centralized systems because

coordination and cooperation between processors are difficult to achieve. Among the factors complicating this design are the failure of processors and the lack of processor synchronization. In this paper, we show how to simplify the design of fault-tolerant protocols using methods that automatically translate protocols tolerant of benign failures into ones tolerant of more severe failures. Such methods provide the abstraction of restricted faulty behavior. We also show how to circumvent the lack of processor synchronization by using logical clocks, which provide the abstraction of perfectly synchronized clocks in solutions to a large class of problems, both in asynchronous and partially synchronized systems.

title: Finding a Minimal Cover for Binary Images: An Optimal Parallel Algorithm
abstract: Given a black and white image, represented by an array of $\surd n x \surd n$ binary valued pixels, we wish to cover the black pixels with a minimal set of (possibly overlapping) maximal squares. It was recently shown that obtaining a minimum cover with squares for a polygonal binary image having holes is NP-hard. We derive an optimal parallel algorithm for the minimal square cover problem, which for any desired computation time T in [log n, n] runs on an EREW-PRAM with (n/T) processors. The cornerstone of our algorithm is a novel data structure, the cover graph, which compactly represents the covering relationships between the maximal squares of the image. The size of the cover graph is linear in the number of pixels. This algorithm has applications to problems in VLSI mask generation, incremental update of raster displays, and image compression.

title: A Provably Good Approximation Algorithm for Optimal-Time Trajectory Planning
abstract: We consider the following problem: given a robot system, find a minimal-time trajectory from a start position and velocity to a goal position and velocity, while avoiding obstacles and respecting dynamic constraints on velocity and acceleration. Based on the theoretical results of [CDRX], we have developed and implemented a new, provably good approximation algorithm for the minimum-time trajectory problem. Our algorithm differs from previous work in three ways. First, it is possible to bound the goodness of the approximation by an error term ϵ. Second, we can polynomially bound the running time (complexity) of our algorithm. Third, we can express the complexity as a polynomial function of the error term. Hence, one supplies the algorithm with the geometric obstacles, dynamics bounds, and the error term ϵ. The algorithm returns a solution that is ϵ-close to optimal, and promises to spend only a polynomial (in $(\frac{1}{\epsilon})$) amount to time computing the answer. In this paper, we describe the algorithm and explain the results in simple terms. We show how it can be applied to robotics, and report on an implementation and experiments.

title: Quantifier Elimination in the First-Order Theory of Algebraically Closed Fields
abstract: We consider the problem of deciding whether a set of multivariate polynomials with coefficients in any field F have a common algebraic solution. In this paper we develop a fast parallel algorithm for solving

this decision problem. Since the proposed algorithm is algebraic, it easily yields a procedure for quantifier elimination in the theory of an arbitrary algebraically closed field. More precisely, we show how to decide whether m polynomials in n variables, each of degree at most d, with coefficients in an arbitrary field F have a common zero in the algebraic closure of F, using sequential time $m^{n + O(1)} d^{n^{2} + O(n)}$, or parallel time $O(n^{3} \log^{3} d \log m)$ with $m^{n + O(1)} d^{n^{2} + O(n)}$ processors, in the operations of the coefficient field F. Using randomization, this may be improved to $m^{O(1)} d^{O(n)}$ time. In addition, the construction is used give a direct EXSPACE algorithm for quantifier elimination in the theory of an algebraically-closed field, which runs in PSPACE or parallel polynomial time when restricted to formulas with a fixed number of alternations of quantifiers.

title: Causally Consistent Recovery of Partially Replicated Logs
abstract: An algorithm is presented for the consistent recovery of replicated data in a client-server system. The algorithm is based on logging and is similar to the optimistic techniques that are well known in the literature. However, unlike in existing optimistic techniques, explicit dependency information is not maintained. Instead, dependency information is estimated from the ordering of messages found in servers' logs. These dependency estimates can, in general, be expensive to compute. It is therefore shown how inexpensive estimates can be applied when a system is well structured.

title: Conditions Unique Graph Embeddings
abstract: The graph embedding problem is that of computing the relative locations of a set of vertices placed in Euclidean space relying only upon some set of inter-vertex distance measurements. This paper is concerned with the closely related problem of determining whether or not a graph has a unique embedding. Both these problems are NP-hard, but the proofs rely upon special combinations of edge lengths. If we assume the edge lengths are unrelated then the uniqueness question can be approached from a purely graph theoretic framework that ignores edge lenghts. This paper identifies three necessary graph theoretic conditions for a graph to have a unique embedding in any dimension. Efficient sequential and NC algorithms are presented for each condition, although these algorithms have very different flavors in different dimensions.

title: Deterministic Simulations of PRAMs on Bounded Degree Networks
abstract: The problem of simulating a PRAM with n processors and memory size $m \geq n$ on an n-node bounded degree network is considered. A scheme is presented which simulates an arbitrary PRAM step in $O ((\log n \log m)/\log \log n)$ time in the worst case on an expander-based network. By extending a previously established lower bound, it is shown that the proposed simulation is optimal whenever $\Omega (n^{1 + \epsilon}) \leq m \leq O(2^{(\log n)\alpha})$ for some $\epsilon greater than O$ and some $\alpha > O$.

title: Bounding the Error in Gaussian Elimination for Tridiagonal Systems
abstract: If $\hat{x}$ is the computed solution to a tridiagonal system $Ax = b$ obtained by Gaussian elimination, what is the "best" bound available for the error $x - \hat{x}$ and how can it be computed efficiently? This question is answered using backward error analysis, perturbation theory, and properties of the LU factorization of A. For three practically important classes of tridiagonal matrix, those that are symmetric positive definite, totally nonnegative, or are M-matrices, it is shown that $(A + E)\hat{x} = b$ where the backward error matrix E is small componentwise relative to A. For these classes of matrix the appropriate forward error bound involves Skeel's condition number cond(A, x), which we show can be computed exactly in $O(n)$ operations. For diagonally dominant tridiagonal A the same type of backward error result holds and we obtain a useful upper bound for cond(A, x) which can be computed in $O(n)$ operations. We also discuss error bounds and their computation for general tridiagonal matrices.

title: Computing Polynomial Composition Factors and Inverses of Automorphisms in Polynomial Time
abstract: The problem of determining when an endomorphism on a polynomial ring is an automorphism and, when it is, the problem of computing its inverse are long standing problems which have received much attention both recently and in the past [BCW], [N], [NS], [SS]. There has also been much attention given recently to various problems relating to the functional decomposition of polynomials [AT], [BZ], [D], [G1],

[G2], [GKL], [KL]. In this paper, we present the first polynomial time algorithm for computing the left composition factor of a multivariate polynomial decomposition and we use that result in the first polynomial time algorithm for computing the inverse of an automorphism on a polynomial ring. Finally, we show how these algorithms can be used to determine when an endomorphism is an automorphism.

title: L-domains and Lossless Powerdomains
abstract: The category of L-domains was discovered by Achim Jung [5] while solving the problem of finding maximal cartesian closed categories of algebraic CPO's and continuous functions. In this note we analyse the properties of the lossless powerdomain construction, that is closed on the algebraic-L-Domains. The powerdomain is shown to be isomorphic to a collection of subsets of the domain on which the construction was done. The proof motivates a certain finiteness condition on the inconsistency relations of elements. It is shown that all algebraic CPO's D whose basis $B(D)$ has property M satisfy the condition. In particular, the coherent L-domains [3] satisfy the condition.

title: The Role of Order in Distributed Programs
abstract: We discuss the role of order in building distributed systems. It is our belief that a "principle of event ordering" underlies the wide range of operating systems mechanisms that have been put forward for building robust distributed software. Stated concisely, this principle is that one achieves correct distributed behavior by ordering classes of distributed events that conflict with one another. By focusing on order, one can obtain simplified descriptions and convincingly correct solutions to problems that might otherwise have looked extremely complex. Moreover, we observe that there are a limited number of ways to obtain order, and that the choice made impacts greatly on performance.

title: Hypercube Algorithms on the Polymorphic Torus
abstract: The Polymorphic Torus architecture is a reconfigurable, massively parallel finegrained system, which in its two-dimensional (N^{2}) case has a lower wiring complexity than, say, hypercubes. However, due to the dynamic connection features at run-time, it allows several parallel structures such as trees, rings, and hypercubes to be emulated efficiently. In this paper, we consider algorithms that are especially well-suited for hypercubes, i.e. algorithms that take advantage of the relatively high connectivity of the hypercube topology, and show how these algorithms attain comparable bounds on a 2-D Polymorphic Torus. In particular,

algorithms for dense matrix vector multiplication (including using 2 orthogonal trees for the matrix-vector case), sparse matrix-vector multiplication, and the FFT are discussed.

title: Computational Complexity of Motion and Stability of Polygons
abstract: The ability to model physical objects and procedures accurately enough to predict their behavior without performing physical experimentation is a fundamental goal of robotics. This facility is prerequisite to offline modeling of assembly tasks, high level robotics languages, and automated assembly planning. This thesis defines and gives algorithms for two classes of physical modeling problems: Mobility problems and Stability problems. The Mobility problem for polygons is that of determining whether, in a configuration of non-intersecting polygons, one or more polygons can be moved (relative to some other polygon in the configuration) without causing intersection. Mobility is shown to be NP-hard. An upper bound for the mobility problem remains an open problem. Translational mobility is the problem of determining whether any polygons can be simultaneously moved by translations without causing intersection. Translational mobility is shown to be NP-complete. Infinitesimal mobility is the problem of determining whether there is a set of velocities for the polygons of the configuration such that no point of a polygon P_{i} that is in contact with another polygon P_{j} has a velocity directed towards the interior of P_{j}. Infinitesimal mobility can be viewed as an approximation to the mobility problem in that any configuration that is mobile is also infinitesimally mobile. Infinitesimal mobility is shown to be NP-complete. The Stability problem for polygons with mass is the problem of determining whether a configuration of polygons is at a static equilibrium point. The stability problem is considered for configurations of polygons with and without friction, and is shown to be NP-hard for both cases. An algorithm is given that distinguishes between configurations that are stable, unstable, and indeterminate. The ability to distinguish indeterminate configurations is important because indeterminate configurations arise when the model of an assembly is not accurate enough to determine whether the assembly is stable. Finally, a restricted class of configurations is developed, the determined configurations, for which a conservative stability problem can be solved in polynomial time. The determined configurations are a natural class in the sense that they preclude a type of contact that "seems unpredictable". If undetermined points are desired or unavoidable, the restricted stability problem can be solved in time exponential in the number of undetermined points in the configuration.

title: Language Features that Support Program Verification (illustrated in PL/C)
abstract: The author of a program can convince its readers (including himself) that it computes as he intended

by writing into the program text a precise description of what it should do. This description can include a clear proof that the program behaves as advertised. In the future, programming languages may offer far more mechanical assistance in expressing, checking, and processing these descriptions than they do now. However, some existing languages, such as PL/C, provide features which help in these tasks considerably. Here we examine such features applied to simple programs of the type traditionally taught in beginning programming classes. We discuss various proposals for expanding programming languages to provide more assistance of this type. Keywords and phrases: program correctness, automatic program verification, Hoare axioms, Scott induction, recursive programs, least number operator, bounded quantifiers, inductive assertion method, programming language design, very high level programmng languages, PL/I, PL/C, macro facilities.

title: A Framework for Learning in Planning Domains with Uncertainty
abstract: Attempts to apply classical planning techniques to realistic environments have met with two major difficulties. The first is that of average-case inadequacy. As one might expect, the (worst-case) computational characteristics of planning problems are ugly at best; a system that is to operate on problems of any reasonable size must rely on heuristics to reduce the average-case complexity of the problem. The second difficulty is that of uncertainty, or what to do when the real world doesn't work as expected. We have shown in earlier work that particular machine learning techniques are a viable means of addressing the problem of average-case inadequacy [Segre88] in domains without uncertainty. This paper describes a planner operating in a realistic environment that is intended to support the same kind of learning. We report some preliminary experimental results comparing our planner with other approaches to planning in the presence of uncertainty.

title: Concurrent Common Knowledge: A New Definition of Agreement for Asynchronous Systems
abstract: In this paper we discuss a new, knowledge-theoretic definition of agreement appropriate to asynchronous systems. This definition has two important features: first, it uses causality, rather than time, in its definition and, second, this form of agreement is attainable. In analogy with common knowledge, it is called concurrent common knowledge. In defining concurrent common knowledge we give a logic with new model operators and a semantics, both of which are based on causality and consequently capture only the relevant structure of purely asynchronous systems. We give general conditions by which protocols can attain concurrent common knowledge and prove that two simple and efficient algorithms do so. We also present several applications of our logic, including necessary and sufficient local preconditions for the concurrent performance of distributed actions. In general, applications that involve all processes reaching agreement about some property of a consistent global state are protocols that use concurrent common knowledge.

title: Time Lower Bounds for CREW-PRAM Computation of Monotone Functions
abstract: It is shown that the time to compute a monotone boolean function depending upon n variables on a CREW-PRAM satisfies the lower bound $T = \Omega$(log l + (log n)/l), where l is the size of the largest prime implicant. It is also shown that the bound is existentially tight by constructing a family of monotone functions that can be computed in $T = O$(log l + (log n)/l), even by an EREW-PRAM. The same results hold if l is replaced by L, the size of the largest prime clause. An intermediate result of independent interest is that $S (n,l)$, the size of the largest minimal vertex cover minimized over all (reduced) hypergraphs of n vertices and maximum hyperedge size l, satisfies the bounds $\Omega(n^{1/l}) \leq S (n,l) \leq O (ln^{1/l}).$

title: Efficient Parallel Algorithms for Covering Binary Images
abstract: Given a black and white image, represented by an array of $\surd$ n x $\surd$ n binary valued pixels, we wish to cover the black pixels with a minimal set of (possible overlapping) maximal squares. It was recently shown that obtaining a minimum cover with squares for a polygonal binary image having holes is NP-hard. We derive a processor-time-optional parallel algorithm for the minimal square cover problem, which for any desired computation time T is [log n, n] runs on an EREW-PRAM with (n/T) processors. We also outline an implementation on a mesh architecture which runs in O ($\surd$ n) time, and is P-T-optimal. Finally, we also show how to obtain a speedup in the running time of our algorithm when polymorphic communication primitives are available on the mesh. The cornerstone of our algorithm is a novel data structure, the cover graph, which compactly represents the covering relationships between the maximal squares of the image.

The size of the cover graph is linear in the number of pixels. This algorithm has applications to problems in VLSI mask generation, incremental update of raster displays, and image compression.

title: Fast Parallel Algorithms for the Modular Decomposition
abstract: A module in a graph is like a black box: all the vertices in the module look the same to vertices not in the module. This paper gives the first NC algorithm for finding the modular decomposition of a graph. The algorithm runs in O(log n) time using $O(n^{3})$ processors on a CRCW PRAM. This decomposition is used to obtain fast sequential and parallel algorithms for solving graph problems on graphs of bounded module size, e.g. the class of cographs where each module with more than one vertex is either disconnected or its complement is disconnected. These graph problems include minimum coloring, maximum clique, matching, Hamiltonian circuit, and maximum cut. Many of these problems can be solved with $O(n^{3})$ processors in O(log n) time. All of them can be solved in NC. Our modular decomposition algorithm can be used to obtain more efficient algorithms for recognizing and orienting comparability graphs.

title: Reversing is Not Inherent in Lexicographical Permutation Generation
abstract: In his comprehensive 1977 survey of permutation generation methods, Sedgewick [4] stated that "(reversing) seems to be inherent in lexicographical (permutation) generation". It is the purpose of this paper to give an algorithm which does not use reversing and to show its relationship to the classical reversing algorithm of Ord-Smith [3]. We also give a number of related algorithms to illustrate the flexibility of the new algorithm.

title: Nuprl as a General Logic
abstract: Study of the architecture and design of proof development systems has become important lately as their use has spread and become closely tied to programming environments. One of the central issues is how to provide a general framework for defining and using a variety of logics in such systems; in particular, whether it is better to staart with a simple core system, such as the typed lambda-calculus with dependent function types, or start with a very rich theory providing a formalized metatheory. The first approach is exemplified by the Edinburgh LF. Here we illustrated the second approach by showing how to use Nuprl

as a framework for defining logics in the style of the LF. Central to the viability of the second apprroach is a method of showing that the encoding of user defined logics in Nuprl is faithful. This paper presents a new semantic method to solve the problem. The method is applicable to the LF as well, and seems simpler than the syntactic methods that previously were used and which seem to hinder the use of rich thoeries as logical frameworks.

title: The Functional Decomposition of Polynomials
abstract: Let $f(\vec{x}), h_{1}(\vec{x}),...,h_{d}(\vec{x})$ and $g(\vec{x})$ be elements of the polynomial ring $K [\vec{x}]$ (or "polynomials over K"). If $f(\vec{x}) = g(h_{1}(\vec({x}),..., h_{d}(\vec{x})),$ then we call $g, h_{1},..., h{d}$ a functional decomposition of f. Polynomial decomposition is an important and interesting problem with a number of applications in computer scinece and computational algebra. Problems related to the decomposition of polynomials have received much attention in the past five years [AT85, BZ85, KL86, Dic87, vzGKL87, vzG87, vzG88, Dic88, KL89] as well as in the less recent past [Rit22, Eng41, Lev41, FM69, DW74]. In fact, the decomposition of polynomials is considered important enough that most major computational algebra systems (SCRATCHPAD II, MAPLE, MATHEMATICA) support polynomial decomposition for univariate polynomials. In this thesis, we examine various problems related to the functional decomposition of polynomials. We will give a brief history of polynomial decomposition, and then give a number of new results, including the first polynomial time algorithms for two important decomposition problems and a proof of the NP-completeness of another interesting polynomial decomposition problem. We will also discuss some ot the applications of polynomial decomposition to problems such as polynomial factorization and computing the inverse of an automorphism over a multivariate polynomial ring. For the latter, we will give the first known polyomial time algorithm.

title: How Accurate is Gaussian Elimination?
abstract: J.H. Wilkinson put Gaussian elimination (GE) on a sound numerical footing in the 1960's when he showed that with partial pivoting the method is stable in the sense of yielding a small backward error. He also derived bounds proportional to the condition number $\kappa(A)$ for the forward error $\| x - \hat{x} \|$, where $\hat{x}$ is the computed solution to $Ax = b$. More recent work has furthered our understanding of GE, largely through the use of componentwise rather than normwise analysis. We survey what is known about the accuracy of GE in both the forward and backward error senses. Particular topics

include: classes of matrix for which it is advantageous not to pivot; how to estimate or compute the backward error; iterative refinement in single precision; and how to compute efficiently a bound on the forward error. Key Words: Gaussian elimination, partial pivoting, rounding error analysis, backward error, forward error, condition number, iterative refinement in single precision, growth factor, componentwise bounds, condition estimator.

title: A Global and Quadratic Affine Scaling Method for Linear L_{1} Problems.
abstract: Recently, various interior point algorithms - related to the Karmarkar algorithm - have been developed for linear programming. In this paper, we first show how this "interior point" philosophy can be adapted to the linear l_{1} problem (in which there are no feasibility constraints) to yield a globally convergent algorithm. We then show that the linear algorithm can be modified to provide a globally and ultimately quadratically convergent algorithm. This modified algorithm is significantly more efficient in practice: we present numerical results to support this claim.

title: Super Edge-Connectivity of Dense Digraphs and Graphs
abstract: Super-λ is a more refined network reliability index than edge-connectivity; G is super-λ if every minimum edge-cut set is trivial (the set of edges incident at a node with the minimum degree δ). This paper clarifies the relations between diameter and super-λ; enlarging the order (the

number of nodes) n under the given maximum degree Δ and a diameter D results in not only maximizing edge-connectivity but also minimizing the number of minimum edge-cut sets, thus attaining super-λ. The following sufficient conditions for digraph and graph G to be super-λ are derived. Digraph G is super-λ if $n greater than \delta (\frac{\Delta^{D-1}-1}{\Delta -1} + 1) + \ Delta^{D-1}$ Digraph G is super-λ if $n greater than \delta (\frac{(\Delta-1)^{D-1}-1}{\Delta -2} + 1) + (\Delta-1)^{D-1}$ These conditions are best possible. From these, de Bruijn digraph $B(d,D)$, Kautz digraph $K(d,D)$, and most of the densest known graphs (listed in [3,9] are shown to be super-λ. Also, the digraph $G^{\ast}_{B}(n,d)$ proposed in [24] as a maximally connected d-regular digraph with quasiminimal diameter (at most one larger than the lower bound) is proved to be super-λ for any d greater than 2 and any order n greater than d^{3}.

title: Partitions and Principles for Secure Operating Systems
abstract: As part of the general goal of providing secure computer systems, the design of verifiably secure operating systems is one of the most important tasks. This paper addresses the problem by defining security in terms of a model and proposing a set of principles which we feel should be satisfied in a secure operating system. Informally, an operating system is secure if its users completely control the use of all information which they introduce. Four key partitions are identified: user interface functions, user invoked services, background services, and the security kernel. Principles are then defined to insure that interface functions provide a safe initial environment for executing user programs, user called services are confined, background services have no access to user information, and the security kernel adequately protects information storage.

title: The Complexity of Quantifier Elimination in the Theory of an Algebraically Closed Field
abstract: This thesis addresses several classic problems in algebraic and symbolic computation related to the solvability of systems of polynomial equations. We develop a parallel algebraic procedure for deciding when a set of multivariate polynomial equations with coefficients in an arbitrary field K have a common solution in an algebraic closure of this field. All computation required by these algorithms takes place over K, the field of definition, and hence does not require explicit construction or approximation of solutions. The decision procedure is subsequently extended to yield an algorithm for deciding when solutions exist for arbitrary Boolean combinations of polynomial equations over an algebraically closed field. Modifications are introduced to compute projections of algebraic and semi-algebraic sets, producing an exponential-space algorithm for determining the truth of sentences in the theory of an arbitrary algebraically closed field. In addition, this algorithm can be executed in polynomial space (PSPACE) when restricted to sentences with a bounded number of quantifier alternations. The algebraic nature of the construction also allows us to develop naturally a quantifier elimination procedure for formulas in this theory within similar time and space bounds. Finally, we show that these results are nearly optimal in a common model of parallel arithmetic computation. We also show how these methods can be used to compute the dimension of an arbitrary algebraic set. A variety of other applications-including the construction and approximation of solutions for systems of multivariate polynomial equations and the isolation of real zones-are investigated.

title: Message Classes: An Approach to Process Synchronization
abstract: In multiprogramming systems, parallel processes compete for access to shared resources and cooperate by exchanging information. Semaphores are a useful means for controlling competition and synchronizing execution and inter-process messages are useful for communication. Neither semaphores nor inter-process message, however, are natural for solving both problems. This paper introduces a new approach, message classes, which combines and extends features of both semaphores and message passing. Using message classes, numerous mutual exclusion, producer/consumer, process communication, and resource allocation problems can be readily solved.

title: Maintaining Tree Projections in Amortized O(log n) Time.
abstract: The projection of a set of marked nodes in a tree can be represented by a structure tree, that is, a subtree containing the marked nodes and the lowest common ancestors of all pairs of marked nodes. As an application modifies a forest of trees by linking and cutting trees and by marking and unmarking nodes, the structure tree associated with each tree must be updated in order to reflect the current set of marked nodes. Previous algorithms have used $O(n)$ time per operation [Hoover 87] to maintain structure trees. This algorithm makes use of self-adjusting binary trees [Sleator and Tarjan 85] and reduces the running time to amortized O(log n) per operation.

title: Automatic Design of Relational Databases
abstract: Advances in relational database technology have made available relational database systems that support state of the art query languages and query processing algorithms. However, because database systems do not include adequate tools for database design, their use and accessibility is hampered by major difficulties that users experience in the process of designing a database. In this dissertation, we present methods and algorithms for automating the design of relational databases and describe a prototype design tool. Unlike researchers who have advocated the use of higher level data models, we focus on the pure relational model, because of its sound theoretical foundation and investigate issues in automatic design of relational databases. We present a new graph representation for functional dependencies, which simplifies and enhances several design algorithms, such as algorithms for computing closures, keys, and projecting dependency sets. We define the basis $B(F)$, a compact representation of F^{+}, which is used to find multiple BCNF decompositions. The basis also provides a way to find the generator of the F-closed sets, an essential component in the computation of Armstrong relations, which are relations representing a set of functional dependencies. We study the inference of multivalued dependencies from an acyclic relational scheme. These multivalued dependencies capture the relationship between the relations in the database. For the inference of functional dependencies within a relation, we optimize previously proposed algorithms. Queries can be used to rate candidate schemes according to how queries perform against them. We present an algorithm for finding the exact query formulation for a particular design, given a scheme independent definition of the query. Multiple ways of accessing the data or no way of accessing the data consistently can be a result indicating that the current design is not valid. Until now, there has been limited experience with feasibility and performance aspects of automatic relational design. We describe a prototype design tool and present a detailed performance study of the dependency inference algorithms implemented in

this prototype.

title: Designing Distributed Services Using Refinement Mappings
abstract: The thesis addresses the design of multiple-server implementations for services in distributed systems-a generalization of the replication management problem. A frequently used correctness criteria for replication management is that clients of a service not be able to distinguish a single-server implementation from on that involves multiple servers. Our approach formalizes this idea. It is based on viewing a single-server implementation of a service as a specification of that service. A multiple-server implementation is considered correct if it implements this single-server based specification. We show how program proof outlines can be viewed as specifications and, using refinement mappings, define what it means for one proof outline to implement another. The notion of a structural refinement, which formalizes the relationship between a program and the result of performing step-wise refinement, is defined. When one proof outline is a structural refinement of the other, simplified proof obligations can be used to show that the one implements the other. Finally, a methodology for designing a multiple-server implementation of a service is presented. The methodology is based on structural refinement and on viewing proof outlines as specifications. A designer defines a refinement mapping to express the relationship between the state space of a given single-server implementation of a service and the state space of the desired multiple-server implementation. Using this refinement mapping, a provably correct multiple-server implementation is derived from the single server one. Different refinement mappings as well as different single-server based specifications result in different implementations. Examples illustrate the concepts and the methodology.

title: Second Order Kinematic Constraint Between Two Bodies Rolling, Twisting and Slipping Against Each Other While Maintaining Point Contact
abstract: The second order kinematic constraint (acceleration constraint) between two rigid bodies that are rolling, twisting, and slipping against each other while maintaining point contact, is derived by differentiation of the first order constraint and by including the geometry of the surfaces at their contact. This constraint is derived with a view to facilitate the simulation of such motion with general purpose dynamics simulators, and more specifically for the Newton dynamic simulator developed at Cornell University. The constraint is first derived for planar motion and then generalized for motion in three dimensions. Some simple, but representative, examples are presented.

title: On Oraclizable Networks and Kahn's Principle

abstract: In this paper we investigate generalizations of Kahn's principle to nondeterministic dataflow networks. Specifically, we show that for the class of "oraclizable" networks a semantic model in which networks are represented by certain sets of continuous functions is fully abstract and has the fixed-point property. We go on to show that the oraclizable networks are the largest class representable by this model, and are a proper superclass of the networks implementable with the infinity fair merge primitive. Finally, we use this characterization to show that infinity fair merge networks and oraclizable networks are proper subclasses of the networks with Egli-Milner monotone input-output relations.

title: From Control Flow to Dataflow
abstract: Are imperative languages tied inseparably to the von Neumann model or can they be implemented

in some natural way on dataflow architectures? In this paper, we show how imperative language programs can be translated into dataflow graphs and executed on a dataflow machine like Monsoon. This translation can exploit both fine-grain and coarse-grain parallelism in imperative language programs. More importantly, we establish a close connection between our work and current research in the imperative languages community on data dependencies, control dependencies, program dependence graphs, and static single assignment form. These results suggest that dataflow graphs can serve as an executable intermediate representation in parallelizing compilers.

title: Completeness of a Temporal Logic for Asynchronous Systems
abstract: In this paper, we define a variant of temporal logic that is designed to capture the temporal and causal aspects of asynchronous distributed systems. In these systems, the usual physical concept of time based upon the notion of a global clock is relegated to a secondary role; causal dependency or necessary temporal precedence is fundamental. Causal dependence is just temporal order locally; globally it is based on communication. An instant of time is replaced by a consistent cut. The semantics of most temporal logics have been based on computation sequences, either linear or branching time. In these models, one views an execution of a system as a single sequence of events. In such models, a "spurious" linearization is introduced, effectively disregarding concurrency. Recently, however, partially ordered models have been considered because, it is argued, that they more accurately represent the system being studied. The main technical contribution of this paper is to show that such a logic is complete for the class of models defined by executions of asynchronous systems.

title: What Should a Roboticist do Next? A Progress Report From the Cornell Computer Science Robotics Laboratory
abstract: The most important intellectual capital of a research laboratory is its coherent vision of science, research and progress. In this progress report, we identify key areas of research, describe the progress we have made in attacking these areas, and discuss our plans for future work. Our primary goal is to bring robotics science closer to its goal of task-level planning. We approach this goal through a blend of theory, implementation, and experimentation. A major impediment to developing truly task-level robotic systems has been the very hard algorithmic problems that arise in task-level robot planning. We have identified several key areas on which to concentrate in developing new algorithmic technologies to crack these problems. Roughly speaking, these areas are: 1. Basic research in compliant motion planning under uncertainty. This

research will result in algorithms and systems that can assemble mechanical parts using compliant motion strategies, despite uncertainty and errors in sensing, control, and modeling. 2. Basic research in planning with full dynamics. It is vital that robots execute tasks quickly, and take dynamics into account. Our research on kinodynamic planning provides the first provably good approximation algorithms for planning nearly time-optimal collision-avoiding paths that respect dynamics bounds. 3. Basic research in design for assembly. The design of mechanical devices and the planning to assemble them should not be independent activities. We introduce a new, fully algorithmic, combinatorially precise approach to designing devices so that they are easy to assemble and (optionally) hard to disassemble. Our analysis can be used to validate good designs, and can be iterated to generate improved designs.

title: Stabilitly and Sequentiality in Dataflow Networks
abstract: The class of monotone input/output automata has been shown in the authors' previous work to be a useful operational model for a dataflow-style networks of communicating processes. An interesting class of problems arising from this model are those that concern the relationship between the input/output behavior of automata to the structure of their transition graphs. In this paper, we restrict our attention to the subclass of determinate automata, which compute continuous functions, and we characterize classes of determinate automata that compute: (1) the class of functions that are stable in the sense of Berry, and (2) the class of functions that are sequential in the sense of Kahn and Plotkin.

title: A Categorical Powerdomain Construction
abstract: The class of countably based bifinites (SFP objects) is the usual mathematical framework for carrying out the constructions that arise in the semantics of programming languages. However, A. Jung showed that the construction used to define the domain-theoretic semantics of polymorphic lambda calculus, is not closed on this category. This motivates the search for a suitable category that is closed under all the constructions used in programming language semantics. T. Coquand developed categories of embeddings as a categorical generalization of the domain-theoretic structures used to give semantics of polymorphism. In this paper, we present a category- theoretic powerdomain construction that is closed on the (extensional) categories of embeddings. The construction is shown to have universal properties that resemble the universal properties of the Plotkin powerdomain.

title: Inductive Inference without Overgeneralization from Positive Examples
abstract: Language learnability is investigated in the Gold paradigm of inductive inference from positive data. Angluin gave a characterization of learnable families in this framework. Here, learnability is studied when the learner obeys certain constraints. These constraints have been suggested by some studies of child language acquisition. Learnable families are characterized for learners with the following types of constraints: (a) conservative, consistent, and responsive, (b) conservative and responsive, (c) conservative and consistent, and (d) conservative. It is shown that the class of learnable families strictly increases going from (a) to (b) and from (b) to (c), while it stays the same going from (c) to (d).

title: A Domain-Theoretic Model for a Higher-Order Process Calculus
abstract: In this paper we study a higher-order process calculus, a restriction of one due to Boudol, and develop an abstract, model for it. By abstract we mean that the model is constructed domain-theoretically and reflects a certain conceptual viewpoint about observability. It is not constructed from the syntax of the calculus or from computation sequences. We describe a new powerdomain construction that can be given additional algebraic structure that allows one to model concurrent composition, in the same sense that Plotkin's powerdomain can have a continuous binary operation defined on it to model choice. We show that the model constructed this way is adequate with respect to the operational semantics. The model that we develop and our analysis of it is closely related to the work of Abramsky and Ong on the lazy lambda calculus.

title: Planning and Executing Robot Assembly Strategies in the Presence of Uncertainty
abstract: Robot control systems are subject to significant uncertainty and error. Typical robots are also equipped with sensors-force sensors, kinesthetic positions sensors, tactile sensors, vision, and so forth. However, these sensors are also subject to significant uncertainty. Finally, the geometrical models of the robot and the environment (part, obstacles, etc.) cannot be exact-they are accurate only to manufacturing tolerances,

or to the accuracy of the sensors used to acquire the models. Uncertainty is an absolutely fundamental problem in robotics, and plans produced under the assumption of no uncertainty are meaningless. What is needed is a principled theory of planning in the presence of uncertainty. Such a theory must not only be computational, but must also take uncertainty into account a priori. In motion planning with uncertainty, we exploit compliant motion-sliding on surfaces-in order to effect a "structural" reduction in uncertainty. Such compliant motion plans can be synthesized from a computational analysis of the geometry of the holonomic constraints. We will present a precise framework for motion planning with uncertainty. In particular, given geometric bounds on the uncertainty in sensing and control, we develop algorithms for generating and verifying compliant motion strategies that are guaranteed to succeed as long as the sensing and control uncertainties lie within the specified bounds. The first results in this theory begin with Lozano-Perez, Mason, and Taylor [LMT], with subsequent contributions by Mason [MA2], Erdmann [E], Donald [D], and others. This research has led to a theoretical computational framework for motion planning with uncertainty, which we explore in this focused survey paper.

title: Quantifiers and Approximation
abstract: We investigate the relationship between logical expressibility of NP optimization problems and their approximation properties. First such attempt was made by Papadimitriou and Yannakakis, who defined the class of NPO problems MAX NP. We show that many important optimization problems do not belong to MAX NP and that in fact there are problems in P which are not is MAXNP. The problems we consider fit naturally in a new complexity class that we call MAX II sub 1. We prove that several natural optimization problems are complete for MAX II sub 1 under approximation preserving reductions. All these complete problems are non-approximable unless P=NP. This motivates the definition of subclasses of MAX II sub 1 that only contain problems which are presumably easier with respect to approximation. In particular, the class that we call RMAX(2), contains approximable problems and problems like MAX CLIQUE that are not known to be non-approximable. We prove that MAX CLIQUE and other natural optimization problems are complete for RMAX(2). All the complete problems in RMAX(2) share the interesting property that they either are non-approximable or are approximable to any degree of accuracy.

title: Sequential Estimation Techniques for Quasi-Newton Algorithms
abstract: Let F be a mapping from real n-dimensional Euclidean space into itself. In terms of solving for a zero of F, the quasi-Newton algorithms are based on the generalized Newton iteration $x_{k+1} = x_{k} - B_{k}^{-1}F(x_{k})$, where $\{B_{k}\}$ is a sequence of nonsingular matrices. In this thesis some geometrical sequential estimation techniques are applied to the calculation of a B_{k} as an estimate for the Jacobian matrix $F'(x_{k})$. The resulting estimators manifest themselves as either rank-one or rank-two, symmetric updates for B_{k}, together with an update for a matrix which is descriptive of the error $E_{k} = B_{k} - F'(x_{k})$. These updates are in fact shown to produce optimal estimates in the sense that they minimize the set size of a certain bound for the error matrix E_{k}. It is shown that the use of the new updates in conjunction with the generalized Newton iteration produces locally and Q-superlinearly convergent algorithms. Moreover, under the requirement that the steps taken by the algorithm satisfy a uniform linear independence condition, it is shown that the R-order of convergence associated with the

symmetric update is at least as large as the positive root of $t^{n+1} - t^{n} - 1 = 0$. A similar but somewhat lower rate of convergence bound is proved for the rank-one update. The symmetric update is implemented in an algorithm for unconstrained optimization which employs Powell's dog-leg step direction/length strategy as a globalization technique. Analysis is presented which, under mild conditions on the function to be minimized, shows that the algorithm is globally and Q-superlinearly convergent. The results of some numerical experiments are presented which show that the algorithm's performance compares favorably with Powell's very successful MINFA.

title: Building Problem Solving Environments In Constructive Type Theory
abstract: We have developed powerful environments within the Nuprl Proof Development System for problem solving in diverse domains. Definitions, proofs, and programs are constructed naturally and at a high-level in these environments, with decision procedures and other tactics providing a degree of automation approaching that found in more specialized theorem provers. Our environments have a wide range of applications that include: Ramsey theory, hardware specification and verification, combinational logic synthesis from proofs, CMOS circuit synthesis from boolean expressions, recursion theory, and partial program development. Several of these applications establish new theorem proving paradigms. We also provide an account of rewriting in type theory and related decision procedures. We have implemented a very general rewrite package for reasoning about arbitrary user defined relations, and we have used this package to construct a number of sophisticated term normalizers, simplifiers, and equality decision procedures. We demonstrate that one of these decision problems deciding if two terms containing otherwise uninterpreted associative-commutative function symbols and commutative variable binding operators are equal, is polynomially equivalent to determining if two graphs are isomorphic.

title: Trade-offs Between Replication and Availability in Distributed Databases
abstract: Distributed databases are generally built on top of standard communication facilities such as leased phone lines. Often several applications, running in different databases, use the same network for their communication. But the applications that run in these databases have grown increasingly more complex and demanding in their availability requirements, often with temporal constraints (such as real-time databases). We argue in this paper that there is a need for dedicated communication networks designed for specific applications. To design such networks, we argue that it is necessary to analyze the data access patterns in the applications that run on the top of the networks. Such analysis would give a network designer an insight into where and how much to replicate the data in the system. Replication can increase availability of data, but too much replication can also hamper it. Thus, for a given application, there exists a right balance

between replication and availability. Our goal is to find this balance and show how to design a network of the cheapest cost that achieves it. In this paper, we take the first step towards the design problem by precisely characterizing the trade-offs between replication and availability and suggest a network design strategy to exploit these trade-offs.

title: Log-Based Recovery in Asychronous Distributed Systems
abstract: Replication has been shown to be an important tool in the design of high- performance and highly-available distributed systems. When applied to data, however, replication significantly complicates the problem of maintaining consistency within a system. This problem is further complicated when repositories of the data can potentially fail and recover. In this dissertation, we describe a log-based mechanism for restoring consistent states to replicated data objects after failures. A variety of techniques have been proposed for implementing consistency in a system. Most of these techniques focus on preserving a form of consistency based on serialization of updates. Although serializable consistency is useful for building a large number of applications, there are also many applications that do not require the full strength of consistency that serializability provides. For these applications, the cost of implementing serializable consistency can be prohibitive. A number of weaker and less expensive consistency forms have therefore been proposed for building such applications. In this dissertation, we focus on preserving a causal form of consistency based on the notion of virtual time. Causal consistency has been shown to apply to a variety of applications, including distributed simulation, task decomposition, and mail delivery systems. Several mechanisms have been proposed for implementing causally consistent recovery, most notably those of Strom and Yemini, and Johnson and Zwaenepoel. Our mechanism differs from these in two major respects. First, we implement a roll-forward style of recovery. A functioning process is never required to roll-back its state in order to achieve consistency with a recovering process. Second, our mechanism does not require any explicit information about the causal dependencies between updates. Instead, all necessary dependency information is inferred from the orders in which updates are logged by the object servers. Our basic recovery technique appears to be applicable to forms of consistency other than causal consistency. In particular, we show how our recovery technique can be modified to support an atomic form of consistency that we call grouping consistency. By combining grouping consistency with causal consistency, it may even be possible to implement serializable consistency within our mechanism.

title: First-Class Synchronous Operations in Standard ML
abstract: In [Reppy88], we introduced a new language mechanism, first-class synchronous operations, for synchronous message passing. In our approach, synchronous operations are represented by first-class values called events. Events can be combined in various ways, allowing a user to define new synchronization abstractions (e.g., remote procedure call), which have equal status with the built-in operations. This paper describes this mechanism and presents a new implementation of events as part of a coroutine package for Standard ML. The coroutine package is written entirely in SML, using first-class continuations, and provides very light-weight processes. First-class continuations provide a natural way to represent events that closely follows an operational semantics for events.

title: Complex Matrix Factorizations with CORDIC Arithmetic
abstract: Matrix factorizations are important in many real-time signal processing applications. In order to improve the performance of these algorithms, special purpose VLSI processor arrays are being developed. Recently, the Coordinate Rotation Digital Computer (CORDIC) algorithms have been applied to the QR Decomposition (QRD) and the Singular Value Decomposition (SVD). In this paper, the CORDIC arithmetic algorithms are extended to deal with complex data. Novel CORDIC VLSI architectures for the QRD of a complex matrix, the Eigenvalue Decomposition of a Hermitian matrix, and the SVD of a complex matrix are presented. These architectures are suitable for VLSI implementation.

title: A Stochastic Analysis of the Performance of Distributed Databases With Site and Link Failures
abstract: A stochastic model for analyzing the performance of a distributed database is proposed. The database is prone to site and link failures, possible leading to a partition of the underlying communication network. The system model is parametrized to support very general assumptions about data replication, transaction access patterns and network connectivity. For concreteness of analysis, a concurrency control protocol based on Thomas' Majority Consensus protocol and the Two-Phase Commit Protocol is used. A new performance measure called expected system degradation is proposed; this measure is a combination of availability of data and the transaction response time; this is the first step towards the ultimate goal of

defining the notion of availability for real-time transaction systems. The model allows a database designer to analyse the expected system performance and choose the right input parameters that emphasize the relative importance of availability and response times.

title: Can LCF Be Topped? Flat Lattice Models of Typed λ-Calculus
abstract: Plotkin, [Plo77], examines the denotational semantics of PCF (essentially typed λ-calculus with arithmetic and looping). The standard Scott semantics $\bigvee$ is computationally adequate but not fully abstract; with the addition of some parallel facilities, it becomes fully abstract, and with the addition of an existential operator, denotationally universal. We consider carrying out the same program for $\diamondsuit$, the Scott models built from flat lattices rather than flat cpo's. Surprisingly, no computable extension of PCF can be denotationally universal; perfectly reasonable semantic values such as supremum and Plotkin's "parallel or" cannot be definable. There is an unenlightening fully abstract extension $\pounds_{A}$(approx), based on Godel numbering and syntactic analysis. Unfortunately, this is the best we can do; operators defined by PCF-style rules cannot give a fully abstract language. (There is a natural and desirable property, operation extensionality, which prevents full abstraction with respect to $\diamondsuit$.) However, we show that Plotkin's program can be carried out for a non-confluent evaluator.

title: Parallel Algorithms for the Split Decomposition
abstract: We give a new $O(n^{2})$ time algorithm for finding Cunningham's split decomposition of an arbitrary undirected graph. We can convert this algorithm to an NC algorithm that uses only $O(n^{3})$ processors. The related composition operation is a generalization of the modular (also called substitution of X-join) composition. The split decomposition is useful in recognizing special classes of graphs, such as circle graphs, which are the intersection graphs of arcs of a circle, and parity graphs, because these graphs are closed under the inverse composition operation. The decomposition can also be used to find NC algorithms for some optimization problems on special families of graphs, assuming these problems can be solved in NC for the indecomposable graphs of the decomposition. A new data structure, which we call a generalized PQ-tree, is used to make the algorithm efficient. Generalized PQ-trees make it easy to find sets that trivially intersect (one set is contained in the other or they are disjoint) each other. All the

calculations on these trees can be done efficiently. Two other important parts of the algorithm are finding a breadth-first search tree and performing a modular decomposition of a graph. These computations are the bottlenecks to an efficient parallel algorithm since they are the only parts of the algorithm where $\omega (n^{2})$ processors are required. However, they can be performed in $O(n^{2})$ time sequentially.

title: Static Scheduling for Dynamic Dataflow Machines
abstract: Dataflow machines can "unravel" loops automatically so that many iterations of a loop can execute in parallel. Unbounded loop unraveling can strain the resources available on the machine and, in extreme cases, deadlock can occur due to overcommitment of resources. Previous efforts to address this problem have focused mainly on runtime mechanisms of debatable utility. Loop bounding, a compile-time technique, controls parallelism by introducing dependencies between loop iterations. The loop is given enough resources for the concurrent execution of some number of iterations, say k. The K + 1st iteration uses the same resources as the first iteration and starts only after the first iteration is complete, and so on. Thus, the granularity of resource allocation is based on the rather arbitrary syntactic notion of a loop iteration. In this paper, we argue that loop bounding can lead to inefficient use of resources and propose an alternative way of compiling loops for pipelined execution. We introduce the notion of a stage decomposition of a loop, which defines a partition of a loop iteration into stages. We show how the problem of choosing a stage decomposition for a particular loop can be tackled by applying compile-time analyses and static scheduling techniques. Such techniques have been developed for scheduling loops on very long instruction word (VLIW) machines which, like dataflow machines, can exploit fine-grained parallelism in programs. These analyses permit the compiler to allocate resources according to expected patterns of usage, thus reducing overall resource requirements. Finally, we show how our schema can be implemented on the Monsoon dataflow machine being built at M.I.T.

title: Processor Efficient Parallel Algorithms for the Two Disjoint Paths Problem, and for Finding a Kuratowski Homeomorph
abstract: We give an NC algorithm for finding vertex disjoint s_{1}, t_{1} and s_{2}, t_{2} paths in an undirected graph G. An important step in solving the general problem is solving the planar case. A new structural property yields the parallelization, as well as a simpler linear time sequential algorithm for this case. We extend the algorithm to the non-planar case by giving an NC algorithm for finding a Kuratowski homeomorph, and, in particular, a homeomorph of $K_{3}, 3$, in a non-planar graph. Our algorithms are processor efficient; in each case, the processor-time product of our algorithms is within a polylogarithmic factor of the best known sequential algorithm.

title: Placing the Largest Similar Copy of a Convex Polygon Among Polygonal Obstacles
abstract: Given a convex polygon P and an environment consisting of polygonal obstacles, we find the largest similar copy of P that does not intersect any of the obstacles. Allowing translation, rotation, and change-of-size, our method combines a new notion of Delaunay triangulation for points and edges with the well-known functions based on Davenport-Schinzel sequences producing an almost quadratic algorithm for the problem. Namely, if P is a convex k-gon and if Q has n corners and edges then we can find the placement of the largest similar copy of P in the environment Q in time $O (k^{4}n \lambda_{4}(kn)$ log$n$), where \lambda_{4} is one of the almost-linear functions related to Davenport-Schinzel sequences. If the environment consists only of points then we can find the placement of the largest similar copy of P in time $O (k^{2}n \lambda_{3}(kn)$ log n).

title: Extending Attribute Grammar and Type Inference Algorithms
abstract: Gated attribute grammars and error-tolerant unification expand upon the usual views of attribute grammars and unification. Normally, attribute grammars are constrained to be noncircular; gated attribute grammars allow fairly general circularities. Most unification algorithms do not behave well when given inconsistent input; the new unification paradigm proposed here not only tolerates inconsistencies but extracts information from them. The expanded views prove to be useful in interactive language-based programming environments. Generalized unification allows the environment to help the user find the sources of type errors in a program, while gated attribute grammars allow the environment to provide an interpreter for incremental reevaluation of programs after small changes to the code. The defining feature of gated attribute grammars is the appearance of a gate attribute (indicating where cycle evaluation should begin and end) within every cycle. Attributes are ordered by collapsing strongly connected components in the dependency graph and topologically sorting the result. The smaller dependency graph for each component (ignoring edges leading to the gate) can be recursively collapsed to provide further ordering. use of the evaluation order defined in this manner allows gated attribute grammars to do without the restrictions on functions within a component needed by the other varieties of circular attribute grammars. Initial and incremental evaluation algorithms are given, as well as a sample grammar allowing an editor for a small language to become an incremental interpreter. Counting unification defines unique solutions to sets of input equations that contain conflicting type information. These solutions are derived from the potential variable constraints implied by the input equations. For each type variable, each branch (a portion of a constraint) is assigned a weight indicating the number of times the input set implied such a constraint. When the input equations are derived from the static analysis of a program, the relative branch weights for a conflicting variable give the overall pattern of uses of that variable and can direct attention to parts of the program that disagree with the majority of uses. A number of error-tolerant unification algorithms are presented.

title: A Fully Abstract Semantics for a Functional Language with Logic Variables
abstract: We present a novel denotational semantics for a functional language with logic variables intended for parallel execution. The intuition behind this semantics is that equations represent equational constraints on data. Thus, a system of equations can be viewed as defining a set of possibly inconsistent constraints. The semantics is couched in terms of closure operators on a Scott domain. This allows one to abstract away from all the complexities associated with operational reasoning expressed in terms of concurrent threads of execution. We define a structural operational semantics for the language that expresses precisely the concurrent execution model that we have in mind. We show that the abstract denotational semantics is fully abstract with respect to the operational semantics. This is surprising, given how very different the two semantic descriptions are. It also shows that thinking in terms of constraints is an accurate substitute for thinking in terms of explicit parallel execution. The proof of full abstraction is complicated by the fact that there are potentially infinite objects in the domain.

title: NC Algorithms for the Clique Separator Decomposition
abstract: We give the first NC algorithm for finding a clique separator decomposition of a graph, that is, a series of cliques whose removal disconnects the graph. This algorithm allows one to extend a large body of results which were originally formulated for chordal graphs to other classes of graphs. Our algorithm is a parallel version of Tarjan's sequential algorithm for solving this problem. The decomposition can also be used to find NC algorithms for some optimization problems on special families of graphs, assuming these problems can be solved in NC for the prime graphs of the decomposition. These optimization problems include: finding a maximum-weight clique, a minimum coloring, a maximum-weight independent set, and a minimum fill-in elimination ordering. We also give the first parallel algorithms for solving these problems by using the clique separator decomposition. Our maximum-weight independent set alforithm applied to chordal graphs yields the most efficient known parallel algorithm for finding a maximum-weight independent set of a chordal graph.

title: Using Bounded Degree Spanning Trees in the Design of Efficient Algorithms on Claw Free Graphs
abstract: Claw-free graphs are graphs that do not have $K_{1,3}$ as an induced subgraph. Line graphs, a special case of claw-free graphs, are the intersection graphs of edges in simple graphs. We show how to compute efficiently in parallel a binary tree that will be a rooted spanning tree of the claw-free graph. Every binary tree contains at least one edge whose removal partitions the tree into two subtrees of nearly equal cardinality, and this separator can be found efficiently in parallel. We solve problems on claw-free graphs by a divide-and-conquer strategy. The advantage of our partition is that the vertices in each set induce a connected subgraph. The problems are solved for the two subgraphs, and then the results are combined to get a solution for the entire graph. Both the problem of finding a perfect matching in claw-free graphs and the problem of reconstructing a root graph from a line graph are amenable to this approach. We present a nearly optimal parallel NC algorithm for computing a perfect matching that runs in time $O(log^{2}n)$ with $O(n + m)$ processors on an EREW PRAM. Also, we present an efficient parallel reconstruction of root graphs form line graphs. If G = (V,E) denotes a line graph, then the algorithm runs in $O(log\vert V \vert)$ time using $O(\vert E \vert)$ processors in the CRCW PRAM model. It is optimal up to a polylogarithmic factor. Previously, it was known how to reconstruct the root graph in NC using a large (though polynomial) number of processors; this is the first algorithm that employs a linear number of processors.

title: On the Representation and Manipulation of Rigid Solids
abstract: Solid modeling studies how to represent geometric properties of solids by computer. A fundamental operation is the construction of representations of solids. Algorithms for set ooperations construct boundary representations of solids from boundary representations of other solids. A correct and efficient intersection

algorithm for polyhedral solids that uses boundary representations is described. A finite-precision implementation of the slgorithm uses incidence tests that use symbolic inference in order to limit errors due to finite-precision approximations. The incidence tests are described and experimental evidence is presented to show that the incidence tests are both empirically reliable and practical. The intersection algorithm uses a new boundary representation called the Star-Edge representation. A complementation algorithm for solids that uses the new representation is given, and an algorithm is given that uses the new representation to determine if two boundary representations describe the same solid. A canonical boundary representation for solids is described and used to prove a lower bound for the same-object problem.

title: Complete, Effective and Abstract System For Reasoning About Networks of Processes
abstract: We present a complete recursive set of axioms for reasoning about networks of bounded asynchronous processes with finite resources. We also present an effective procedure for hiding internal channels of a network. Our processes use finite resources and bounded asynchronous communication. Such processes and networks can be physically realized. Our processes can be specified by means of regular expressions and do not require the full theory of arithmetic. The assertion language we use exploits this fact and allows us to specify all such processes and networks and obtain a complete and effective use of Ehrenfeucht games. An algorithm for channel hiding follows from the way these processes can be modeled.

title: An Efficient Algorithm for One-Step Planar Compliant Motion Planning with Uncertainty
abstract: Uncertainty in the executin of robot motion plans must be accounted for in the geometric computations from which plans are obtained, especially in the case where position sensing is inaccurate. We give an $O(n^{2} log n)$ algorithm to find a single commanded motion direction which will guarantee

a successful motion in the plane from a specified start to a specified goal whenever such a one-step motion is possible. The plans account for uncertainty in the start position and in robot control, and anticipate that the robot may stick on or slide along obstacle surfaces with which it comes in contact. This bound improves on the best previous bound by a quadratic factor, and is achieved in part by a new analysis of the geometric complexity of the backprojection of the goal as a function of commanded motion direction.

title: An Improved Algorithm for Labeling Connected Components in a Binary Image
abstract: In this note, we present an improved algorithm to Schwartz, Sharir and Siegel's algorithm [8] for labeling the connected components of a binary image. Our algorithm uses the same bracket marking mechanism as is used in the original algorithm to associate equivalent groups. The main improvement of our algorithm is that it reduces the three scans on each line required by the original algorithm in its first pass into only one scan by using a recursive group-boundary dynamic tracking technique, while maintaining the computation on each pixel during scan still a constant time. This algorithm is fast enough to handle images in real time and simple enough to allow an easy and very economical hardware implementation.

title: Implementing Metamathematics as an Approach to Automatic Theorem Proving
abstract: A simple but important algorithm used to support automated reasoning is called matching: given two terms it produces a substitution, if one exists, that maps the first term to the second. In this paper the matching algorithm is used to illustrate the approach to automating reasoning suggested in the title. In Section 3 the algorithm is derived and verified in the Nuprl proof development system following exactly an informal presentation of it in Section 2. The example serves to introduce a particular automated reasoning system, Nuprl, as well as the idea of deriving programs from constructive proofs. The treatment of this example also suggests how these systems can be soundly extended by the addition of constructive metatheorems about themselves to their libraries of results.

title: Guaranteed-Quality Triangular Meshes
abstract: There are a number of applications for which it is desirable to divide a given region in the plane into nicely shaped triangles. One important such application is the finite element method, a method widely used to obtain approximate solutions to a wide variety of engineering problems. For this kind of application, not just any triangulation will do; error bounds are best if all the triangles are as close as possible to equilateral triangles. Presently, either these triangles are produced by hand or they are produced automatically using one of a number of heuristic techniques. For these heuristic techniques, certain cases can require human intervention to eliminate flat triangles. In this paper, we present an efficient new technique (based on Delauney triangulations) for automatically producing desirable triangulations. Unlike most previous techniques, this one comes with a guarantee: the angles in the resulting triangles are all between 30 and 120 degrees, and the edge lengths are all between h and 2h where h is a parameter chosen by the user.

Additional useful properties include (1) the worst-case time to produce a triangulation is linear in the final number of triangles, and (2) the user can control the element density, producing smaller triangles in areas where more accuracy is desired.

title: Exploiting Fast Matrix Multiplication Within the Level 3 BLAS
abstract: The Level 3 BLAS (BLAS3) are a set of specifications of Fortran 77 subprograms for carrying out matrix multiplications and the solution of triangular systems with multiple right-hand sides. They are intended to provide efficient and portable building blocks for linear algebra algorithms on high performance computers. We describe algorithms for the BLAS3 operations that are asymptotically faster than the conventional ones. These algorithms are based on Strassen's method for fast matrix multiplication, which is now recognized to be a practically useful technique once matrix dimensions exceed about 100. We pay particular attention to the numerical stability of these "fast BLAS3". Error bounds are given and their significance is explained and illustrated with the aid of numerical experiments. Our conclusion is that fast BLAS3, although not as strongly stable as conventional implementations, are stable enough to be suitable for many applications.

title: Information Retrieval Based on Axiomatic Decision Theory
abstract: The main objective of this paper is to establish a coherent framework for information retrieval based on the axiomatic decision theory. In information retrieval one has to deal with two difficult problems (knowledge representation and query formulation), both of which are absent in conventional database systems. It is argued that the axiomatic decision theory provides a useful framework to study these complex issues. Two quantitative representation systems are introduced. One is developed from the expected utility model and the other is derived from the concepts of evidential reasoning. An inductive learning algorithm is suggested for constructing a user query. The experimental results seem to provide some support for the theoretical arguments presented here. Although the focus in this paper is mainly on information retrieval, the current work may be viewed as a preliminary effort towards unifying symbolic and numeric reasoning with incomplete or uncertain information.

title: An Architecture for General Purpose Physical System Simulation--Integrating Geometry, Dynamics, and Control

abstract: Simulation of physical systems has long been of interest to scientists and engineers, and significant efforts have been directed toward the development of general purpose computer aided design and analysis systems. To date, however, success has been largely limited to the production of tools suited only for particular aspects of design: computer aided design systems have primarily emphasized specification of geometry; simulation systems from the mechanical engineering field have concentrated mainly on formulation and integration of an unchanging set of equations describing object behavior; and work by computer graphics and animation researchers has been aimed at producing good-looking animations without much regard for whether the generated motions were physically realistic. Flexible systems integrating all aspects of design and analysis have not yet been built. This thesis addresses the issues involved in developing fundamentally more powerful simulation systems. A system architecture for general purpose physical system simulation is proposed, and a prototype implementation, the newton system, is described. The architecture is based on a rich model-based object representation and provides a level of automatic analysis that encourages the kind of experimentation necessary for successful design. In particular, it is argued that by using geometric modeling techniques to include a full description of object geometry, previously difficult-to-incorporate simulation system features, such as collision detection and resolution, can be handled much more naturally. The Newton architecture incorporates a uniform exceptional event handling mechanism that allows the system to respond to a variety of simulation events that necessitate modification of object behavior descriptions. Combined with a general method for the formulation of object motion equations, the event handling mechanism supports automatic handling of collisions, changing contact relationships, control program state changes, and other events that can cause discontinuities in object motions.

title: Experiments with Generalized Binary Probabilistic Independence Model
abstract: This paper reports experiments with the generalized binary probabilistic independence model in which more complete statistical information is used. Two basic sets of experiments, referred to as nonpredictive and predictive, have been performed on two standard test collections. In the nonpredictive experiments, the complete relevance information was used to determine the optimal performance of the model. On the other hand, in the predictive experiments only partial relevance information was used to demonstrate the predictive power of the model. Although a simple method for estimating the parameters was used in the designed tests, significant improvements were obtained for both test collections. These preliminary results suggest that further work on the generalized model is worthwhile.

title: On the Use of Clustered File Organization in Information Search and Retrieval
abstract: In modern retrieval environments, collection searches are normally conducted on-line under user control. Iterative collection searches can then be performed where tentative queries are initially processed, to be successively improved and refined during the search process. When searches are carried out directly by the users, classified document organizations are especially useful, because collection browsing becomes possible, and access is provided to complete groups of related documents. The state-of-the-art in automatic document classification is summarized in the present study, and evaluation data are provided to demonstrate the effectiveness and efficiency of clustered file search operations.

title: Towards a Notion of Module for Data Abstraction
abstract: Traditionally, programming languages support data abstraction through some kind of module construct for partitioning large systems into manageable units. These constructs typically control access to data since program decomposition is usually guided by information hiding. As mechanisms for encapsulating implementations of data types, however, such constructs are too inflexible. Substituting one implementation (module) for another, in a client, may require the client to be revised for reasons related to representation. A more flexible notion of module is presented that is designed solely for the purpose of encapsulating implementations of data types. D.3 [Software]: Programming Languages; D.3.2 [Programming Languages]: Language Classifications - applicative languages; D.3.3 [Programming Languages]: Language Constructs - abstract data types, modules, packages; D.3.4 [Programming Languages]: Processors - compilers; F.3 [Theory of Computation]: Logics and Meanings of Programs; F.3.3 [Logics and Meanings of Programs]: Studies of Program Constructs - type structure. Additional Key Words and Phrases: representation independence, modules, functional programming, types.

title: Formalization and Evaluation of Linear Relevance Feedback
abstract: This study outlines an adaptive method which constructs improved query vectors based on the user preference judgments on sample document pairs. In particular, the user states that some documents are preferred to other documents and the system is then expected to rank the preferred documents ahead of the others. In the adaptive system, all needed parameter values are provided within the model, and a solution query vector is constructed under well defined conditions. Certain relationships between the new adaptive and the conventional relevance feedback systems are discussed and evaluation data are provided to demonstrate the effectiveness of the system.

title: The Role of Inhibition in Asynchronous Consistent-Cut Protocols
abstract: We present results relevant to the development of consistent-cut protocols. Consistent-cut protocols are those which are based on finding a consistent global state in an underlying distributed computation; they are used for a variety of applications such as system checkpointing and deadlock detection. We formally define what it means for a protocol to be non-inhibitory, which intuitively means that it does not prevent any actions from occurring in an underlying system computation. We prove that there is no non-inhibitory consistent-cut protocols for FIFO systems of one message per bidirectional channel (up to $\frac {1}{2} (n^{2} - n$, for completely connected networks). We present two protocols, one non-inhibitory requiring up to two messages between each pair of neighboring nodes in a network and the other inhibitory and requiring only $3(n - 1)$ messages total. In most networks, these results illustrate a tradeoff between the amount of necessary communication and the willingness to inhibit actions of the underlying system. Additionally, our inhibitory protocol also works for non-FIFO systems, thus illustrating that the inhibitory condition is exactly what is required to develop consistent-cut protocols for non-FIFO systems which satisfy our model.

title: Non-Canonical Extensions of Bottom-Up Parsing Techniques
abstract: A bottom-up parsing technique which can make non-leftmost possible reductions in sentential forms is said to be non-canonical. Nearly every existing parsing technique can be extended to a non-canonical method which operates on larger classes of grammars and languages than the original technique. Moreover, the resulting parsers run in time linearly proportional to the length of their input strings. Several such extensions are defined and analyzed from the points of view of both power and decidability. The results are presented in terms of a general bottom-up parsing model which yields a common decision procedure for testing membership in many of the existing and extended classes.

title: The Expressive Power of Delay Operators in SCCS
abstract: We investigate the relative expressive power of finite delay operators in SCCS. These were introduced by Milner and by Hennessy to study fairness properties of processes in the context of SCCS. We show that the context sensitive delay operator introduced by Hennessy is more expressive than the finite delay operator introduced by Milner. This result is closely related to recent results by Panangaden and Stark on the expressive power of fair merge in asynchronous dataflow (Kahn) networks. It indicates that the expressiveness results obtained there are not sensitive to the precise computational model since SCCS, unlike Kahn networks, is synchronous and permits expansion of recursively defined processes.

title: Harary Networks: Connectivity for Highly Available Real-Time Distributed Databases
abstract: A methodology, called network designing by the desirable partition, for designing Underlying communication networks for distributed databases is proposed. It exploits the fact that in most real-life databases, the data is not fully replicated, and the transactions access pattern is highly local. The methodology consists of identifying a desirable partition of the sites based on the notion of dependencies between sites; the latter is defined by the replication of data and the transaction data access patterns. A hierarchical communication network, called a Harary Network, is then constructed for the identified partition. The notion of desirability takes into account the cost of connection, and thus provides the most desirable construction for a given cost. The method is probabilistic in the sense that in presence of failures, the probability of the occurrence of the desirable partition is higher than that of all other partitions; this results in very high expected availability. It is shown that for most intuitive formulations of the problem, finding the most desirable partition is NP-Hard. However, good and often optimal approximation algorithms exist

for this problem. The methodology is particularly suited for designing communication support for real-time distributed databases.

title: Verification Conditions for ω-Automata and Applications to Fairness
abstract: We present sound and complete verification conditions for proving that a program satisfies a specification definied by a deterministic Rabin automaton. Our verification conditions yield a simple method for proving that a program terminates under general fairness constraints. As opposed to previous approaches, our method is syntax-independent and does not require recursive applications of proof rules. Moreover using a result by Safra, we obtain the first direct method for proving that a program satisfies a Buchi automaton specification. Finally, we show that our method generalized two earlier methods.

title: Compiler Parallelization of SIMPLE for a Distributed Memory Machine
abstract: In machines like the Intel iPSC/2 and the BBN Butterfly, local memory operations are much faster than inter-processor communication. When writing programs for these machines, programmers must worry about exploiting spatial locality of reference. This is tedious and reduces the level of abstraction at the which the programmer works. We are implementing a parallelizing compiler that will shoulder much of that burden. Given a sequential, shared memory program and a specification of how data structures are to be mapped across the processors, our compiler will perform process decomposition to exploit locality of reference. In this paper, we discuss some experiments in parallelizing SIMPLE, a large scientific benchmark from Los Alamos, for the Intel iPSC/2.

title: Type Definitions in Polya
abstract: The programming language Polya maintains a clear separation between a type and its implementation through a new construct called the transform. Polya allows user to define their own data types and transforms to implement them. The type definition facility of Polya has capabilities not found in existing languages; in short, it allows a more comprehensive description of the properties that determine whether a program is well-formed. Two such properties are the scope of variables and the bounded polymorphic nature of some operations. One can specify the scope of any local variables that an operation introduces and express that the well-formedness of an operation depends on whether some overloaded function name stands for a function of a certain type. Also novel, is the ability to define literal classes for types and to specify both an abstract

and concrete syntax for operations. With these capabilities, it becomes possible to define the syntax of a block-structured language within Polya itself.

title: Parallel Resultant Computation
abstract: A resultant is a purely algebraic criterion for determining when a finite collection of polynomials have a common zero. It has been shown to be a useful tool in the design of efficient parallel and sequential algorithms in symbolic algebra, computational geometry, computational number theory, and robotics. We begin with a brief history of resultants and a discussion of some of their important applications. Next we review some of the mathematical background in commutative algebra that will be used in subsequent sections. The Nullstellensatz of Hilbert is presented in both its strong and weak forms. We also discuss briefly the necessary background on graded algebras, and define affine and projective spaces over arbitrary fields. We next present a detailed account of the resultant of a pair of univariate polynomials, and present efficient parallel algorithms for its computation. The theory of subresultants is developed in detail, and the computation of polynomial remainder sequences is derived. A resultant system for several univariate polynomials and algorithms for the gcd of several polynomials are given. Finally, we develop the theory of multivariate resultants as a natural extension of the univariate case. Here we treat both classical results on the projective (homogeneous) case, as well as more recent results on the affine (inhomogeneous) case. The u-resultant of a set of multivariate polynomials is defined and a parallel algorithm is presented. We discuss the computation of generalized characteristic polynomials and relate them to the decision problem for the theories of real closed and algebraically closed fields.

title: Complexity of Finitely Presented Algebras
abstract: An algebra $\cal A$ is finitely presented if there is a finite set G of generator symbols, a finite set O of operator symbols, and a finite set Γ of defining relations $x \equiv y$ where x and y are well-formed terms over G and O, such that $\cal A$ is isomorphic to the free algebra on G and O modulo the congruence induced by Γ. The uniform word problem, the finiteness problem, the triviality problem (whether $\cal A$ is the one element algebra), and the subalgebra membership problem (whether a given element of $\cal A$ is contained in a finitely generated subalgebra of $\cal A$) for finitely presented algebras are shown to be $\leq^{m}_{\log}$-complete for P. The schema satisfiability problem and schema validity problem are shown to be $\leq^{m}_{\log}$-complete for NP and co-NP, respectively, Finally, the problem of isomorphism of finitely presented algebras is shown to be polynomial time many-one equivalent to the problem of graph isomorphism.

title: Flow in Planar Graphs with Vertex Capacities
abstract: Max-flow in planar graphs has always been studies with the assumption that there are capacities only on the edges. Here we consider a more general version of the problem when the vertices as well as edges have capacity constraints. In the context of general graphs considering only edge capacities in not restrictive, since one can reduce the vertex capacity problem to the edge capacity problem. However, in the case of planar graphs this reduction does not maintain planarity and cannot be used. We study different versions of the planar flow problem (all of which have been extensively investigated in the context of edge capacities).

title: Deterministic Simulations of Shared Memory on Bounded Degree Networks
abstract: The Parallel Random Access Machine (PRAM) is an abstract parallel machine consisting of a synchronous collection of n processors connected to a shared memory of m cells. The essential feature of the PRAM is that the processors can access any n-tuple of distinct cells in a single machine cycle. While the PRAM is an attractive and widely used framework for the design and analysis of parallel algorithms, it does not reflect the constraints of realistic multiprocessors. This thesis explores the problem of efficient deterministic simulations of PRAM computations on bounded degree networks of processors, a model of parallel machines closer to what can be built in practice. It is shown that an arbitrary step of a PRAM with n processors and $m \geq n$ cells of shared memory can be simulated in O($log($(m/n)$ log n/log log n + log n log log n (log log (m/n) - log log log n)) time in the worst-case on an n-node bounded degree network with a particular expander-based structure. This simulation is more efficient than all deterministic simulations previously known both with respect to time and space. In the case where m/n is polylogarithmic in n, the worst-case time to simulate a single PRAM step is at most O(log n log log n) which is within a factor of $O(log log n the diameter of the network. The space requirements for our algorithm are at most O(m(log $(m/n))^{3})$ overall. The simulation may also be adapted to run on to an n-processor augmented mesh-of-trees architecture with a running time of O (log n log log n (log log (m/n) - log log log n) + log $(m/n))$ Overall, these results suggest that, in principle at least, it is feasible to provide the abstraction of a shared memory on distributed models of parallel computation with only modest degradation in performance in the worst case.

title: On Laziness and Optimality in Lambda Interpreters: Tools for Specification and Analysis
abstract: In this paper, we introduce a new formal system, ΛCCL, based on Curien's Categorical Combinators [Cur86a]. We show that ΛCCL has properties that make it especially suitable for analysis and implementation of a wide range of λ-reduction schemes using shared environments, closures, or λ-terms. In particular, the term structure of $\Lamda CCL$ is very closely related to the structure of existing abstract machines for λ-reduction. ΛCCL is powerful enough to mimic arbitrary (strong) reduction in the λ-calculus, yet in contrast to the systems in [Cur86a] it is also confluent (on ground terms).As an example of the practical utility of this formalism, we use it to

specify a simple lazy interpreter for the λ-calculus, whose correctness follows trivially from the properties of ΛCCL. We then describe a labeled variant of $\Lambda CCL, \Lambda CCL^{L}$, which can be used as a tool to determine the degree of "laziness" possessed by various λ-reduction schemes. In particular, ΛCCL^{L} is applied to the problem of optimal reduction in the λ-calculus. A reduction scheme for the λ-calculus is optimal if the number of redex contractions that must be performed in the course of reducing any λ-term to a normal form (if one exists) is guaranteed to be minimal. Results of Levy [Lev78, Lev80] showed that for a natural class of reduction strategies allowing shared redexes, optimal reductions were, at least in principle, possible. He conjectured that an optimal reduction strategy might be realized in practice using shared closures and environments as well as shared λ-terms. However, using ΛCCL^{L}, we show that the sharing allowed by environments and closures in ΛCCL as implemented using standard term graph-rewriting techniques [BvEG^{+}87] is insufficient to implement optimal reduction.

title: A Globally and Superlinearly Convergent Algorithm for Convex Quadratic Programs with Simple Bounds
abstract: We present a globally and superlinearly convergent algorithm for solving convex quadratic programs with simple bounds. We develop our algorithm using a new formulation of the problem: the minimization of an unconstrained piecewise quadratic function that has the same optimality conditions as the original problem. The major work at each iteration is the Cholesky factorization of a positive definite matrix with the size and structure of the Hessian of the quadratic. Hence our algorithm is suitable for solving large sparse problems and for implementation on parallel computers. We implemented our algorithm and tested it on a sequential computer on a variety of dense problems, and we present numerical results which show that our algorithm solves many problems quickly. Keywords: quadratic programming, interior point methods, simple bounds, box constraints, large sparse minimization.

title: Incremental Attribute Evaluation and Multiple Subtree Replacements
abstract: The standard model for incremental attribute evaluation allows single subtree replacements followed by attribute reevaluation to restore consistency to a derivation tree. This thesis advocates an extended model that allows multiple subtree replacements. A static (tree-walking) algorithm for performing incremental updating after such changes is developed. The algorithm cannot be used with all attribute grammars, but is restricted to grammars contained in the new class of "globally partitionable attributer grammars" (GPAGs). A test for determining whether an attribute grammar is GPAG is described. The multiple subtree replacement algorithm (GPAG-evaluate) in this thesis improves on two shortcomings of existing algorithms. First, many evaluators have a running time that depends linearly on the size of the derivation tree of on the number of concurrent subtree replacements. GPAG-evaluate has a running time of O(log $n \cdot$ |AFFECTED|), where n is the number of nodes in the derivation tree and AFFECTED is the set of attributes needing reevaluation. Second, experience with incremental, attribute grammar-based environments demonstrates that dynamic evaluators are noticeably slower than static evaluators because they require time-consuming data structure manipulations. Most existing algorithms for multiple subtree replacements are dynamic, but GPAG-evaluate is static. A second problem treated in this thesis is asynchronous subtree replacements, that

is, allowing changes to be made while propagation continues after previous changes. A method for analyzing the efficiency of asynchronous subtree replacement algorithms is presented. An asynchronous evaluator (ASYNCH-evaluate) is described that, like GPAG-evaluate, guarantees that no attributes will be evaluated unnecessarily. Under some restrictions, ASYNCH-evaluate is as efficient as GPAG-evaluate. In particular, propagation in trees containing dynamically generated, nonlocal dependency edges can be supported. Both GPAG-evaluate and ASYNCH-evaluate must find lowest common ancestors of nodes in a tree where subtree replacements were made. A simple technique performs this operation in time $O(n)$. To make the evaluators more efficient, this thesis describes an algorithm that uses self-adjusting binary trees to perform the necessary operations in amortized O(log n) time. These operations are not restricted to attributed derivation trees, but can be used for any application using trees.

title: Provably Good Approximation Algorithms for Optimal Kinodynamic Planning for Cartesian Robots and Open Chain Manipulators
abstract: We consider the following problem: given a robot system, find a minimal-time trajectory from a start state to a goal state, while avoiding obstacles by a speed-dependent safety-margin and respecting dynamics bounds. In [CDRX] we developed a theoretical, provably good approximation algorithm for the minimum-time trajectory problem for a robot system with decoupled dynamics bounds (e.g. a point robot in). This algorithm differs from previous work in three ways. It is possible (1) to bound the goodness of the approximation by an error term ϵ; (2) to polynomially bound the computational complexity of our algorithm; and (3) to express the complexity as a polynomial function of the error term. Hence, given the geometric obstacles, dynamics bounds, and the error term ϵ, the algorithm returns a solution that is ϵ-close to optimal and requires only a polynomial (in ($\frac{1}{\epsilon}$)) amount of time. We extend the results of [CDRX] in two ways. First, we reanalyze the [CDRX] algorithm for robots with decoupled dynamics bounds. We halve the exponent in the polynomial bounds and prove a better approximation accuracy. These new results indicate that an implementation of the theoretical algorithm could be reasonable. We report on a preliminary implementation of the extended algorithm and experiments. Second, we extend [CDRX] to d-link, revolute-joint 3D robots will full rigid body dynamics. Specifically, we first prove a generalized trajectory- tracking lemma for robots with coupled dynamics bounds. Then, using this result we describe polynomial-time approximation algorithms for Cartesian robots obeying L_{2} dynamics bounds and open kinematic chain manipulators with revolute and prismatic joints; the latter class includes most industrial manipulators. We obtain a general $O(n^{2}$(log$n$) ($\frac{1}{\epsilon})^{6d-1})$ algorithm, where n is the geometric complexity.

title: Parallel Algorithms for Intersection Graphs
abstract: Intersection graphs have often been used to model special structure in graph problems for both practical and theoretical reasons. Often problems can be solved efficiently for a restricted class of graphs that are provably hard for graphs in general. In this thesis, we examine parallel (i.e. NC) algorithms for exploiting the special structure of different types of intersection graphs to solve common graph problems. First, we show how to recognize whether a graph belongs to one of the special families of intersection graphs. Only after this has been done can we take advantage of the properties of a class of intersection graphs. Let $\cal F$ be a family of nonempty sets. Then the intersection graph of $\cal F$ is obtained by representing each set in $\cal F$ by a vertex and connecting two vertices if and only if their corresponding sets have a nonempty intersection. In this dissertation, several types of intersection graphs will be examined, among them interval, comparability, chordal, path, and circle graphs. Interval and comparability graphs arise often when solving scheduling problems. Chordal graphs have applications in solving sparse systems of linear equations and in relational database theory. Each of these classes of intersection graphs is closed under a natural graph composition operation, namely one of modular composition, clique identification, and split composition. In this thesis, we show that the number of intersection representations for a graph in one of these classes depends on how the graph was composed from indecomposable graphs. Also, we show how to efficiently decompose any graph (i.e. perform that inverse of the above composition operations) in parallel. Often if we can solve a problem efficiently on the indecomposable pieces of a graph, then we can solve this same problem efficiently on the graph itself in parallel. Thus we can extend many of our results on special classes of intersection graphs to more general classes of graphs.

title: Preconditioning for Boundary Integral Equations (Preliminary Version)
abstract: We propose new classes of preconditioners for the linear systems arising from a boundary integral equation method. The problem under consideration is Laplace's equation in three dimensions. The system arising in this context is dense and unsymmetric. Our preconditioners, which are based on solving small linear systems at each node, reduce the number of iterations in some cases by a factor of 20. Two iterative methods are considered: conjugate gradient on the normal equations and GMREES of Saad and Shultz. For a simple model problem, we demonstrate the exact relationship between the preconditioners and the resulting condition number of the preconditioned system is decreased by a factor asymptotically greater than any constant.

title: Limit Operators and Convergence Measures for ω-Languages with Applications to Extreme Fairness
abstract: Methods of program verification for liveness and fairness rely on measuring "progress" of finite computations towards satisfying the specification. Previous methods are based on explaining progress in terms of well-founded sets. These approaches, however, often led to complicated transformations or inductive applications of proof rules. Our main contribution is a simpler measure of progress based on an ordering that is not well-founded. This ordering is a variation on the Kleene-Brouwer ordering on nodes of a finite-path tree. It has the unusual property that for any infinite ordered sequence of nodes, the liminf of the node depths (levels) is finite. This novel view of progress gives a precise mathematical characterization of what it means to satisfy very general program properties. In particular, we solve the problem of finding a progress measure for termination under extreme fairness.

title: The Inhibition Spectrum and the Achievement of Causal Consistency
abstract: We consider the problem of distinguishing causally-consistent global states in asynchronous distributed systems. Such states are fundamental to asynchronous systems, because they correspond to possible simultaneous global states; their detection arises in a variety of distributed applications, including global checkpointing, deadlock detection, termination detection, and broadcasting. We consider a spectrum of protocol capabilities based on the type of inhibition that occurs, i.e. the extent to which the protocol delays events of the underlying system. For the first time we distinguish local versus global inhibition and prove fundamental relationships between these concepts and determining causally-consistent states. In local inhibition, processors only delay events until they have performed some number of local actions; in global inhibition, they delay events while waiting for some communication from other processors. Based on a variety of system and protocol characteristics, including the ability to locally or globally inhibit particular types of events, we give several new impossibility results and examine some existing protocols. We are then able to present a thirty-six-case summary of protocols and impossibility results for the determination of causally-consistent states as a function of those characteristics. In particular, we demonstrate that local inhibition is necessary and sufficient to solve this problem for general FIFO systems, while global send inhibition is necessary for general non-FIFO systems.

title: Convergence Measures
abstract: General methods of verification for programs defining infinite computataions rely on measuring progress or convergence of finite computations towards satisfying the specification. Traditionally, progress is measured using well-founded orderings, but this often involves syntactic transformations. Our main result is that program verification can take place by direct measurement of convergence for programs that are analytic ($\sum^{1}_{1}$) sets and specifications that are coanalytic ($\prod^{1}_{1}$) sets. We use orderings that are not well-founded, but that ensure well-foundedness of limits of finite trees. Our results can also be seen as a new approach to parts of descriptive set theory. In fact, Souslin's Theorem-that every set in $\sum^{1}_{1} \cap \prod^{1}_{1}$ is Borel-is a simple corollary of our main result.

title: Planar Sliding With Dry Friction 1: Limit Surface and Moment Function
abstract: We present two geometric descriptions of the net frictional force and moment between a rigid body and a planar surface on which it slides. The limit surface LS, from classical plasticity theory, is the surface in load space which bounds the set of all possible frictional forces and moments that can be sustained by the frictional interface. Zhukovskii's moment function is the net frictional moment about the body's instantaneous center of rotation (COR) as a function of its location. Both of these descriptions implicitly contain the full relation between slip motion and frictional load. While Zhukovskii's moment function applies only to ordinary isotropic Coulomb friction, the limit surface applies to a wider class of friction laws that includes, for example, contact mediated by massless rigid wheels. Both the limit surface and the moment function can be used to deduce results concerning the motion of sliding rigid bodies.

title: Planar Sliding With Dry Friction 2: Dynamics of Motion
abstract: Some problems in the dynamics of sliding of planar rigid bodies are treated by geometric methods based on the limit surface description of friction (Goyal, Ruina, Papadopoulos [1990]). The problems we consider, where the normal force is known a priori, have unique solutions although the friction force (and torque) may be a discontinuous function of the direction of motion. When a freely sliding object comes to rest it always does so with one of several definite ratios of translation to rotation. These special generalized velocity directions, termed eigen-directions, depend on the friction law used, the contact pressure distribution and the mass distribution. The eigen-directions correspond to local extrema of the generalized frictional load |P| on the limit surface, i.e. to direction in load space where P is parallel to the generalized motion direction q. For most objects, if the radius of gyration is sufficiently larger than the radius of the contact region final motion is always pure rotation about the center of mass; if the mass distribution is sufficiently central the final motion is a pure translation. A simple model of a car with locked rear wheels shows the effect of speed and orientation on skid stability at finite speeds. Sliders have a propensity to rotate about points of support.

title: Brown's Method and Some Generalizations, With Applications to Minimization Problems
abstract: Newton's method attempts to find a zero of $f \in C^{1}(IR^{n})$ by taking a step which is intended to make all components of f vanish at once. In this respect Newton's method processes the components of f in parallel. Contrasting to this, Brown's method and the generalizations thereof considered in this thesis process the components of f serially, one after another. One major iteration of these methods may be described as follows: given the starting point (i.e. current major iterate) y_{0}, linearize the first component f_{1} of f at y_{0} and find a point y_{1} in the $n-1$ dimensional hyperplane H_{1} on which this linearization vanishes; in general, having found a point $y_{k} (1 \leq k less than n)$ in the $n-k$ dimensional hyperplane H_{k} on which the heretofore constructed linearizations vanish, restrict f_{k+1} to H_{k}, linearize this restriction at y_{k}, and find a point y_{k+1} in the $n-(k+1)$ dimensional hyperplane H_{k+1} on which this linearization vanishes; stop when Y_{n} has been found and let y_{n} be the next major iterate. When f is a general nonlinear function and finite differences are used to construct the linearizations, this approach must do work equivalent to approximating only about half the components of f' and thus requires only about half as many function evaluations per major iteration as the corresponding finite difference Newton's method, while still enjoying the same rate of local convergence.

title: Optimal Enclosure Problems
abstract: We consider the following "fence enclosure" problem: Given a set S of n points in the plane with values $v_{i} \geq 0$, we wish to enclose a subset of the points with a fence (a simple closed curve) so as to maximize the "value" of the enclosure. The value of the enclosure is defined to be the sum of the values of the enclosed points minus the cost of the fence. We consider various versions of the problem, such as allowing S to consist of points and/or simple polygons. Other versions of the problems are obtained by restricting the total amount of fence available and also allowing the enclosure to consist of up to K connected components. We show that the problem for a bounded length fence is NP-complete . Additionally we provide polynomial-time algorithms for many versions of the fence problem when an unrestricted amount of fence is available. When the set S consists of points and the fence is unrestricted in length we solve the problem via an $O(n^{3})$ time sweep-line algorithm; we give an alternative $O(n^{3})$ time algorithm based on finding shortest paths in directed graphs, and generalize it to handle various cases in which S is a set of polygons. When $K greater than 1$ components are permitted we obtain a polynomial-time algorithm (for consistent K).

title: Determining Frictional Inconsistency for Rigid Bodies is NP-Complete
abstract: The computational complexity of computing the forces between bodies in contact is presented. The bodies are restricted to be perfectly rigid bodies that contact at finitely many points. It has been known for some time that under the Coulomb model of friction, some configurations of bodies are inconsistent; that is, no contact forces satisfying the constraints of the Coulomb friction model exist for the configuration. The main result of this paper is a proof that determining if a configuration is inconsistent is an NP-complete problem. An immediate corollary of this proof is that computing the contact forces for a configuration of bodies is NP-hard. Computing contact forces remains NP-hard even if configurations are restricted to be consistent.

title: Parallelizing Programs with Recursive Data Structures
abstract: Interference estimation is a useful tool in developing parallel programs and is a key aspect of automatically parallelizing sequential programs. Interference analysis and disambiguation mechanisms for programs with simple data types and arrays have become a standard part of parallelizing and vectorizing compilers. However, efficient and implementable techniques for interference analysis in the presence of dynamic data structures have yet to be developed. This thesis addresses the problem of estimating interference and parallelizing programs in the setting of an imperative language that supports dynamic data structures. By focusing on analysis methods for recursively defined pointer data structures such as trees and DAGs, we have developed efficient and implementable interference analysis tools and parallelization techniques. The interference analysis methods are based on estimating the relationships between accessible nodes in a data structure. We define a data abstraction for estimating relationships that leads to an efficient interference analysis. Analysis functions are provided for SIL, a simple imperative language that includes conditionals, loops and recursive procedures. The analysis is proven sound with respect to the standard semantics for SIL. Based on the interference analysis tools, a collection of parallelization techniques are developed and the coarse-grain techniques are used to develop a simple system for parallelizing programs for a shared memory machine. The analysis techniques and parallelization system have been implemented, and examples illustrating the methods are provided.

title: Interactive Query Formulation and Feedback Experiments in Information Retrieval
abstract: The effective use of information retrieval systems by end-users has been limited by their lack of knowledge on the particular organization of the databases searched and by their limited experience on how to formulate and modify search statements. This thesis explores and evaluate two mechanisms to improve retrieval performance by end-users. The first mechanism complements the formulation of a query by allowing users to interactively add term phrases. These phrases are generated either from the query text of from known relevant documents. This addition of term phrases to a query is suggested by the term discrimination model as a precision enhancement device. An interactive front-end for the SMART information retrieval system was developed to perform the interactive experiments needed to evaluate different phrase addition strategies.

The second aspect of retrieval improvement studied is the evaluation of two database organizations that can be used to obtain new relevant documents by looking in the neighborhood of known relevant documents, browsing. Browsing in cluster hierarchies and nearest-neighbor networks is compared to relevance feedback in non-restrictive experiments. The results obtained for the phrase addition methodology showed that simple non-interactive addition of phrases can perform as well as interactive addition. Even an optimal selection of the phrases based on the relevant documents not yet retrieved, did not significantly improve performance over simply adding all the phrases generated. Many useful phrases are not selected by users because they look like random association of terms. The usefulness of these phrases comes from the fact that either they are pieces of larger (semantically meaningful) phrases, or they are made up of local synonyms specific to the document collection used. The browsing experiments in cluster hierarchies and nearest-neighbor networks showed that the second organization consistently performs better than relevance feedback in different collections. Cluster browsing is more dependent on the characteristics of the collections; but when the circumstances are favorable, cluster browsing can produce larger improvements on retrieval that network browsing. Retrieval in both structures is much faster than relevance feedback since only a small portion of the database needs to be inspected.

title: Directory Design and Record Allocation for List and Cluster Files
abstract: Most file organizations for on-line econdary key retrieval consist of two subcomponents - a structural file and a data file. The structural file provides, a physical access path in the data base for each query, so that searches can be restricted to small portions of the data file. The data file contains the data records where information is stored. Hence, the file design problem consists of (1) an efficient design of the structural file, and (2) an allocation of data records in the data file so that a given set of data records can be jointly retrieved at mimimum cost. List structure organizations and clustered organizations are shown to be important structures for secondary key retrieval. This thesis studies the design aspects of the structural and data files for both of the above organizations. The most popular list structure files are the inverted list and the multilist organizations. It is shown that either organization is a special case of a new class of hybrid list organizations. File elements in this class are characterized by a list length parameter $\cal l_{th}$, and a list is stored as an inverted list or as a multilist depending on whether its length is larger than $\cal l_{th}$ or not. Analytical and simulation results indicate that neither a pure inverted list organization nor a pure multilist organization is normally the best choice for all elements in the class. A new method is also introduced for the structure of combined indices for list structure files. A combined index is created only if its component keys co-occur frequently in the queries. Experimental results show that such combined indices do improve the search performances for both inverted list and multilist organizations. Search methods and physical implementations of clustered organizations are discussed. The balancing of cluster trees is shown to be an important concept. A search model is established to obtain optimal branching ratios for cluster trees. The optimal branching ratio is seen to be dependent on certain statistical characteristics of the data base. The last part of the thesis concerns itself with the arrangement of records in the dataa file. The data records are assigned to blocks in the disk like devices. The goal is to minimize the average number of block accesses in processing the query set in the system. This problem turns out to be a polynomial complete problem. Heuristic algorithms are therefore used for the record block assignment. Experimental results show that a record organization produced by the heuristic algorithms is more efficient than a random assignment of records to the blocks.

title: On Computing Boolean Connectives of Characteristic Functions
abstract: We study the existence of polynomial time Boolean connective functions for languages. A language L has an AND function if there is a polynomial time f such that $f(x,y) \in L \Longleftrightarrow x \in L$ and $y \in L$. L has an OR function if there is a polynomial time g such that $g(x,y) \in L \Longleftrightarrow x \in L$ or $y \in L$. While all NP-complete sets have these functions, we show that Graph Isomorphism, which is probably not complete, also has them. We characterize the complete sets for the classes D^{P} and $P^{NP[O(log n)]}$ in terms of AND and OR, and we relate these functions to the structure of the Boolean hierarchy and the query hierarchies. We show that the sets that are complete for levels above the second level of the Boolean hierarchy do not have AND and OR unless the polynomial hierarchy collapses. We show that most of the structural properties of the Boolean hierarchy and query hierarchies depend only on the existence of AND and OR functions for NP-complete sets.

title: A Quadratically-Convergent Algorithm for the Linear Programming Problem with Lower and Upper Bounds
abstract: We present a new algorithm to solve linear programming problems with finite lower and upper bounds. This algorithm generates an infinite sequence of points guaranteed to converge to the solution; the ultimate convergence rate is quadratic. The algorithm requires the solution of a linear least squares problem at each iteration - it is similar in this respect to recent interior point and "Karmarkar-like" methods. However, the algorithm does not require feasibility of the iterates; instead, monotonic decrease of an augmented linear l_{1} function is maintained. A penalty parameter is not required. This method is particularly attractive for large-scale problems in that the number of iterations required to obtain high accuracy is relatively insensitive to problem size and is typically quite small. We provide results of numerical experiments.

title: Full Abstraction and Fixed-Point Principles for Indeterminate Computation
abstract: Recently, there has been much interest in the problem of finding semantic models for various kinds of concurrent systems. A common property of concurrent systems is indeterminate behavior, either because of unpredictable interactions between processes, or because of abstractions removing the temporal details of the interaction. As a result, the study of the semantics of indeterminacy is necessary and important to the understanding of concurrency. The goal of any semantic model is that is capture our intuitions about the

operational behavior of the underlying system and aid in our reasoning about it. Two properties of semantic models that we find useful in achieving this goal are full abstraction and fixed-point principles. In this thesis we investigate the problem of finding semantic descriptions with these properties for indeterminate systems. We begin by looking at a simple imperative language containing unbounded indeterminacy, based on one studied by Apt and Plotkin. We use category-theoretic techniques to develop a fixed-point semantics that, while not fully abstract, reduces to a fully abstract semantics via a simple abstraction functor. We then concentrate on the more general setting of dataflow networks and the hierarchy of indeterminate merge primitives. We show that the straighforward generalization of Kahn's semantics based on the input-output relations fails to be compositional for any class of indeterminate dataflow networks, thereby providing a model considerably more general than Kahn's. This generalization has the drawback that it does not have a simple fixed-point principle. We proceed to study a class of networks that models purely internal indeterminacy, called oraclizable networks, and show that for this class a generalization of Kahn's semantics to sets of functions is both fully abstract and has a natural fixed-point principle. We also show that the oraclizable networks are in fact universal for this representation. Finally, we use this representation to compare the class of oraclizable networks to other classes, and discover new relations among the classes.

title: A Global and Quadratically-Convergent Method for Linear L_{∞} Problems
abstract: We propose a new global and quadratically convergent algorithm for the linear l_{∞} problem. This method works on the piecewise l_{∞} problem directly by generating descent directions - via a sequence of weighted least squares problems - and using piecewise linear linesearches to ensure a decrease in the l_{∞} function at every step. We prove that ultimately full Newton-like steps are taken where the Newton step is based on the complementary slackness condition holding at the solution. Numerical results suggest a very promising method; the number of iterations required to achieve high accuracy is relatively insensitive to problem size.

title: Real-Time Robot Motion Planning Using Rasterizing Computer Graphics Hardware
abstract: We present a real-time robot motion planner that is fast and complete to a resolution. The technique is guaranteed to find a path if one exists at the resolution, and all paths returned are safe. The planner can handle any polyhedral geometry of robot and obstacles, including disjoint and highly concave unions of polyhedra. The planner uses standard graphics hardware to rasterize configuration space obstacles into a series of bitmap slices, and then uses dynamic programming to create a navigation function (a discrete vector-valued function) and to calculate paths in this rasterized space. The motion paths which the planner produces are minimal with respect to an L_{1} (Manhattan) distance metric that includes rotation as well as translation. Several examples are shown illustrating the competence of the planner at generating planar rotational and translational plans for complex two and three dimensional robots. Dynamic motion sequences including complicated and non-obvious backtracking solutions, can be executed in real time.

title: On the Structure of Uniquely Satisfiable Formulas
abstract: This paper presents some new results on the computational complexity of the set of uniquely satisfiable Boolean formulas (USAT). Valiant and Vazirani showed that USAT is complete for the class D^{P} under randomized reductions. In spite of the fact that the probability bound of this reduction is low, we show that USAT captures many properties possessed by D^{P} many-one complete sets. We show that the structure of USAT can affect the structure of D^{P} and the entire Polynomial Hierarchy (PH) as well. That is, 1. if USAT $\equiv^{P}_{m} \overline{USAT}$, then D^{P} = co-D^{P} and PH collapses. 2. if USAT $\in$ co-D^{P}, then PH collapses. 3. if USAT is closed under disjunctive reductions, then PH collapses. The third result implies that the probability bound in the Valiant-Vazirani reduction cannot be amplified by repeated trials unless the Polynomial Hierarchy collapses. These results show that even sets complete under "weak" randomized reductions can capture properties of many-one complete sets.

title: Text Linking and Retrieval Experiments for Textbook Components
abstract: Experiments are described designed to retrieve individual paragraphs of textbook material in answer to user-submitted queries. The retrieval strategies are based on the global comparison of paragraph texts, as well as on the local processing of text sentences. Furthermore, the retrieved items may be freely chosen, or may alternatively be restricted to certain areas in a clustered arrangement of book paragraphs. The retrieval results indicate that high retrieval values are obtainable for the more refined retrieval strategies, ranging between 0.70 and 0.80 in search precision.

title: Aspects of the P-Norm Model of Information Retrieval: Syntactic Query Generation, Efficiency, and Theoretical Properties
abstract: A practical information retrieval system must be easy to use by untrained users, and it must provide prompt responses to a user's search requests. In this thesis, these practical aspects of the p-norm model of information retrieval are explored. In addition, a study of theoretical properties of the p-norm model is presented. A syntactic method for generating p-norm queries from parse trees generated by the PLNLP syntactic analyzer is presented. The effectiveness of the syntactically generated queries is shown to be comparable to the effectiveness of manually constructed queries, and much better than that of statistically generated queries. The efficiency of a p-norm retrieval is significantly improved with a new p-norm retrieval algorithm which evaluates the entire document collection in one recursive traversal of the query tree. This algorithm is compared against the straightforward algorithm, which requires a traversal of the query tree for each document that is evaluated. The new algorithm is shown to be better both asymptotically and experimentally. The infinity-one model is introduced as a means of approximating the p-norm model without requiring exponentiation. Experimental results show that infinity-one retrieval is essentially as effective as p-norm retrieval, but much faster. List pruning methods for further efficiency improvements are also introduced and are shown to reduce retrieval time significantly without affecting the precision of top-ranked documents. The retrieval time of the infinity-one model with list pruning is shown to be comparable to that of pure Boolean retrieval. A theoretical study is also presented in which certain Boolean algebra properties, such as associativity, are shown to be unsatisfiable by any extended Boolean system with weak operators. The p-norm model is shown to satisfy all those properties that can be satisfied. In addition, the p-norm model is evaluated with respect to the Waller-Kraft wish list for extended Boolean systems.

title: On IP=PSPACE and Theorems with Narrow Proofs
abstract: Very recently, it was shown that the class of languages with interactive proofs, IP, is exactly the class PSPACE. This surprising result elegantly places IP in the standard classification of feasible computations. Furthermore, the IP = PSPACE result reveals some very interesting and unsuspected properties of mathematical proofs. In this column, we define the width of a proof in a formal system $\cal F$ and show that it is an intuitively satisfying and robust definition. Then, using the IP = PSPACE result, it is seen that the width of a proof (as opposed to the length) determines how quickly one can give overwhelming evidence that a theorem is provable without showing the full proof.

title: Incremental Reduction in the Lambda Calculus

abstract: An incremental algorithm is one that takes advantage of the fact that the function it computes is to be evaluated repeatedly on inputs that differ only slightly from one another, avoiding duplication of common computations. We define here a new notion of incrementality for reduction in the untyped λ-calculus and describe an incremental reduction algorithm, Λ^{inc}. We show that Λ^{inc} has the desirable property of performing non-overlapping reductions on related terms, yet is simple enough to allow a practical implementation. The algorithm is based on a novel λ-reduction strategy that may prove useful in a non-incremental setting as well. Incremental λ-reduction can be used to advantage in any setting where an algorithm is specified in a functional or applicative manner.

title: On Kleene Algebras and Closed Semirings
abstract: Kleene algebras are an important class of algebraic structures that arise in diverse areas of computer science: program logic and semantics, relational algebra, automata theory, and the design and analysis of algorithms. The literature contains at several inequivalent definitions of Kleene algebras and related algebraic structures [2, 13, 14, 5, 6, 1, 9, 7]. In this paper we establish some new relationships among these structures. Our main results are: (1) There is a Kleene algebra in the sense of [6] that is not *-continuous. (2) The categories of *-continuous Kleene algebras [5, 6], closed semirings [1, 9] and S-algebras [2] are strongly related by adjunctions. (3) The axioms of Kleene algebra in the sense of [6] are not complete for the universal Horn theory of the regular events. This refutes a conjecture of Conway [2, p. 103]. (4) Right-handed Kleene algebras are not necessarily left-handed Kleene algebras. This verifies a weaker version of a conjecture of Pratt [14].

title: Black-box complexity of local minimization
abstract: We study the complexity of local minimization in the black-box model, that is, the model in which the objective function and possibly its gradient are available as external subroutines. This is the model used, for example, in all the optimization algorithms in the 1983 book by Dennis and Schnabel. Our first main result is that the complexity grows polynomially with the number of variables n, in contrast to other related black-box problems (global minimization, Brouwer fixed points) for which the worst case complexity is exponential in n. Our second contribution is the construction of a family of functions that are bad cases for all possible black-box local optimization algorithms.

title: An Evaluation of Text Matching Systems for Text Excerpts of Varying Scope
abstract: When large text collections must be processed, it is not possible to limit the scope of the subject matter of interest. In such a situation the standard content analysis methods that are based on the use of knowledge bases to represent the relevant subject areas are not applicable. Necessarily, the text themselves must then serve as the main basis for the content analysis operations. Experiments are described in this note designed to evaluate text matching operations for text excerpts of varying scope, including in particular text paragraphs and text sentences extracted from book size materials. The evaluation shows that when the global text similarity between distinct text paragraphs is high, while at the same time local similarities also exist for particular text sentences included in these paragraphs, the presumption is that the paragraphs cover related subject matter. One concludes that text matching systems may prove useful for text linking and information retrieval.

title: On Some Central Problems in Computational Complexity
abstract: In this thesis we examine some of the central problems in the theory of computational complexity, like the trade-offs between time and memory, the power of nondeterminism and parallelism, and the speed gained by adding new operations to random access machines. Our main result is the cahracterization of the power of multiplication in random access acceptors: we show, in Chapter 3, that for such models nondeterministic and deterministic computations are polynomially related and that there is a polynomial relationship between the amount of time required for acceptance by random access machines with multiplication, and the amount of tape required by Turing machines. Thus, the additional power gained by using multiplication is the same as that of memory over time (if any). We derive similar results for some other interesting instruction sets. We also have some results for probabilistic and nondeterministic computations: we define threshold machines and show how probabilistic Turing machines may simulate them, and exhibit a set of complete problems for threshold machines. For nondeterministic computations, we present a hierarchy of the elementary recursive languages obtained by polynomially bounded quantification over objects of higher and higher type, which represent nondeterministic time bounded computations with larger and larger bounds. Finally, we discuss some deterministic computations, and conclude with a look at some open problems.

title: Tools for Distributed Application Management
abstract: Distributed application management consists of monitoring and controlling an application as it executes in a distributed environment. It encompasses such activities as configuration, initialization, performance monitoring, resource scheduling, and failure response. In this paper we describe the Meta system: a collection of tools for constructing distributed application management software. Meta provides the mechanism, while the programmer specifies the policy for application management. The policy is manifested

as a control program which is a soft real-time reactive program. The underlying application is instrumented with a variety of built-in and user- defined sensors and actuators. These define the interface between the control program and the application. The control program also has access to a database describing the structure of the application and the characteristics of is environment. Some of the more difficult problems for application management occur when pre-existing, nondistributed programs are integrated into a distributed application for which they may not have been intended. Meta allows management functions to be retrofitted to such programs with a minimum effort. Keywords: Distributed application management, configuration management, distributed operating systems, dynamic reconfiguration, monitoring distributed systems, rule-based systems, Isis.

title: Knowledge and Inhibition in Asynchronous Distributed Systems
abstract: In an asynchronous distributed system, processes communicate only via message passing along channels with unbounded transmission time. Relative process speeds are arbitrary and processes do not have access to a common clock. For such systems, a useful means of providing temporal structure is the causality relation. Causality imposes a partial order on the events of an execution based on the necessity of certain events preceding other events. Causality can be used to give a sensible definition of a distributed global state in an asynchronous system, known as a consistent cut. We present a new knowledge-theoretic logic, with formal semantic definitions, for reasoning about causality and consistent cuts. The logic includes concurrent common knowledge, a new form of distributed agreement, which has an analogous role to that of common knowledge in synchronous systems. It is shown to be a necessary and sufficient condition for performing concurrent actions in asynchronous systems, and has a role in many distributed applications such as checkpointing, deadlock detection, and broadcasting. Concurrent common knowledge is also shown to be attainable by class of protocols termed distinguishable-consistent-cut-protocols or DCCPs. We examine four simple and efficient DCCPs and trade-offs between them. These trade-offs involve message

complexities, necessity of FIFO channels, and the degrees to which events of the underlying system are suspended during execution of the protocols. We call such suspensions inhibition and formally define multiple forms of inhibition that are used in distributed protocols. We classify the DCCPs in this work according to their inhibitory characteristics, and prove new results which demonstrate close relationships between inhibition and the existence of DCCPs.

title: Design of a Microprocessor Driven Generic Controller for a Mobile Robot Base
abstract: The primary project goal is to design and fabricate a controller to be used in an autonomous mobile robot which is consistent with the generic controller concept set forth by the Mobile Robotics Group. A generic controller must be capable of controlling interfacing units such as sonar and motor drive systems without any hardware modifications. Thus, any sensor or actuator applicable for use in mobile robotics can be utilized by providing the appropriate interface to, and programming for, the generic controller. Communication between generic controllers is needed to pass data from sensors to actuators. The most important design considerations are interface flexibility, size, power consumption, and robustness. The generic controller provides the following capabilities as specified by the Mobile Robotics Group. These include interboard communication capability, on-board memory, debug and download capability through the use of a dedicated communication channel, a pulse width generator for motor control, an interrupt arbitration scheme, and a multi-port I/O device with separate ports for an array of light emitting diodes, preset dual inline switches and external pendent control capability.

title: Efficient Parallel Algorithms for Disjoint Paths and Connectivity
abstract: This thesis is concerned with the problem of designing efficient parallel algorithms for various graph-theoretic problems. Our larger goal is to identify "tools" that would be useful in designing parallel algorithms for various graph-theoretic problems. We show that the concept of bridges plays a crucial role in the design of algorithms for the kinds of problems we consider. The specific problems we consider are the following. We give an NC algorithm for finding vertex-disjoint s_{1}, t_{1} and s_{2}, t_{2} paths in an undirected graph. An important step in solving the general problem is solving the planar case. A new structural property yields the parallelization, as well as a simpler linear time sequential algorithm for this case. We extend the algorithm to the non-planar case by giving an NC algorithm for finding a Kuratowski homeomorph, and, in particular, a homeomorph of $K_{3,3,}$ in a non-planar graph. We also present an

efficient parallel algorithm for testing whether a graph is k vertex-connected. To develop our algorithm we design an efficient parallel algorithm for the following disjoint $s-t$ paths problem: Given a graph and two specified vertices s and t, find k vertex-disjoint paths between s and t, if they exist. If no such paths exist, find a set of at most k - 1 vertices whose removal disconnects s and t. We show how to modify the algorithm to find k edge-disjoint paths, if they exist. This yields an efficient parallel algorithm for testing whether a graph is k edge-connected. Finally, we describe more applications of the disjoint $s-t$ paths algorithm. This algorithm is also used as a subroutine in the algorithm for the two paths problem mentioned earlier.

title: Flexible Concurrency Control by Reasoning About Database Queries and Updates
abstract: A number of database management problems involve reasoning about queries and updates. Concurrency control is the most important example: two transactions should not be executed simultaneously if it is possible that an update command issued by one transaction might change information used in answering a query issued by the other. Existing concurrency control schemes are based on the idea of protecting discrete items of data. This thesis describes a concurrency control scheme called adaptive locking that is based instead on logical reasoning. The central notion is that of independence. Informally, a query is independent of an update if executing the update cannot change the result of evaluating the query. First the general properties of the concept of independence are investigated, using a formal model-theoretic definition in the context of deductive databases. Then proof-theoretic sufficient conditions are obtained for

the independence of queries and updates. These results apply to arbitrary queries and updates, and they take into account integrity constraints and recursive rules. For the special case where a query and an update are both specified by conjunctive relational algebra expressions, a decision procedure for independence is given. The procedure is of practical use because typically it requires linear time, and it produces answers that are precise enough to be relied upon. The procedure takes into account functional dependencies, so it constitutes a solution to an open problem identified by Blakeley, Coburn, and Larson. It is of theoretical interest for two reasons. First, its quadratic worst-case time complexity cannot be improved unless the reachability problem for directed graphs can be solved in sublinear time. Second, it applies to the widest possible natural class of queries, since deciding independence is NP-hard for nonconjunctive queries and updates.

title: The Expressiveness of Indeterminate Dataflow Primitives
abstract: This thesis establishes that there are different kinds of indeterminacy in an asynchronous distributed computation setting by studying expressiveness and inexpressiveness situations. We use a particular model of asynchronous distributed computation, called the dataflow model. This model very naturally portrays the situation of autonomous computing agents communicating asynchronously to each other along fixed one-way paths called channels. The nature of computation is studied both in an operational setting, and in a more abstract setting, and equivalences are proved between them so that one may freely move between them. We use the operational semantics of Lynch and Stark to describe the operational behavior of processes in the dataflow model. We show how one can abstract out the low-level operational behavior and obtain "traces" that are well-suited for reasoning about network behavior, once the properties of tract sets have been fully described using the operational semantics from which they arise. We consider several forms of indeterminacy in this context, modeling them as different fairness guarantees on merge primitives, that try to merge two sequences of values into one, and choice primitives, that split one sequence of values into two. The main contribution here has been to show that there is a surprising hierarchy of different notions of indeterminacy. This cannot simply be described using degree of branching - bounded versus unbounded. We use the trace of sets of these primitives for these proofs. The description of this hierarchy clarifies the expressibility situation for indeterminacy in an asynchronous distributed setting. It is our hope that by concentrating on specific properties of agents that are really relevant to their behavior in any particular system, one would obtain simpler and more convenient semantics to describe this behavior. In most of this thesis, we consider static dataflow - a fixed set of processes communicating along a fixed set of channels. In one of the final chapters, we consider recursively defined dataflow networks whose behavior involves the

creation of processes and channels. We prove the equivalence of an operational and an abstract semantics there for determinate networks.

title: A Note on Tape Bounds for SLA Language Processing
abstract: In this note we show that the tape bounded complexity classes of languages over single letter alphabets are closed under complementation. We then use this result to show that there exists an infinite hierarchy of tape bounded complexity classes of sla languages between log n and log log n tape bounds. We also show that every infinite sla language recognizable on less than log n tape has infinitely many different regular subsets, and, therefore, the set of primes in unary notation, P, requires exactly log n tape for its recognition and every infinite subset of P requires at least log n tape.

title: Parallel Evaluation in Attribute Grammar-Based Systems
abstract: Attributed context-free grammars provide a rigorous basis for the semantic analysis and translation of tree-structured objects and have been used to build a variety of systems. A number of programming language compiler, compiler generators, and language-based editor generators employing attribute grammars have been described in the literature. Many of these systems make use of l-ordered attribute grammars, attribute grammars for which particularly efficient methods for attributing derivation trees have been described. Derivation trees representing constructs of only moderate size may contain thousands of nodes and tens of thousands of attribute instances, and attribution of such trees on uniprocessor systems may require a significant amount of time. One possibility for reducing this time is to find techniques that exploit opportunities for parallelism in the attribution process and allow attribution to be performed on multiprocessor systems. Such techniques would permit attribute grammars to serve as a rigorous foundation for the development of parallel compilation systems and other parallel applications. We present several methods for the parallel attribution of trees derived from l-ordered attribute grammars. These methods take advantage of parallelism implicit in the attribution process and, thus, do not require any special considerations to be taken when constructing grammars. Methods appropriate for use on tightly - and loosely-coupled multiprocessor architectures and for use when complete and incremental tree attribution are required are presented. We present preliminary performance results obtained from implementations of some of the methods on a simple shared-memory multiprocessor simulator embedded within an attribute grammar-based editor generator system. The results suggest that the methods may provide useful reductions in attribution time in some cases.

title: Bisimulation Can't Be Traced
abstract: In the concurrent languages CCS, two programs are considered the same if they are bisimilar. Several years and many researchers have demonstrated that the theory of bisimulation is mathematically appealing and useful in practice. However, bisimulation makes too many distinctions between programs.

There are two programs P and Q which are not bisimilar, but nontheless are interchangeable: one may be substituted for the other anywhere in a CCS program and no difference can be seen. Bisimulation is thus not fully abstract. We consider the problem of adding operations to CCS to make bisimulation fully abstract. It is trivial to add an operation achieving full abstraction, but this operation is rather peculiar. We show that bisimilation is not fully abstract with respect to any extension of CCS by CCS-like operations. We give a formal description of "CCS-like," as GSOS and argue by proofs and counterexamples that this is indeed the right class. In the proof of non-full-abstraction a coarser version of bisimulation arises, a notion called ready simulation. We investigate the theory of ready simulation, showing that it possesses the basic properties which make bisimulation attractive. Like bisimulation, it possesses equivalent relational and logical characterizations; it has two additional equivalent characterizations as congruence with respect to all GSOS languages, and with respect to CCS extended by process copying and controlled communication operations. In particular, it is fully abstract for a sensible extension of CCS. As a corollary, we show that bisimulation cannot be fully abstract with respect to any CCS-like languages, observing traces.

title: Extracting Constructive Content from Classical Proofs
abstract: This thesis is concerned with the relationship between classical and constructive mathematics. It is well-known that in many constructive logics, we can interpret mathematical sentences as program specifications, and we can interpret a constructive proof of such a sentence as a program which meets this specification. It is also well-known that many classical logics do not have the property, as shown by Brouwer's counterexamples to some theorems of analysis. Kreisel and Friedman showed that for certain classes of sentences (Π_{2}^{0}), the classical theories conservatively extend their constructive counterparts, and furthermore give effective translations from classical proofs to constructive proofs. This thesis consists of two parts. In the first, we describe our implementation of Friedman's translation results, and their use in translating Higman's Lemma, a nontrivial theorem of combinatorics. To do this, we delineate a subtheory of a constructive type theory (Nuprl) for which Friedman's translation is guaranteed to succeed. We also extend the Nuprl type theory with impredicative Π-quantification, and use this to provide a classical proof of Higman's Lemma, which we go on to mechanically translate to a constructive proof. In the second part, we discuss connections that we have discovered between Friedman's translation and a standard compilation technique, continuation-passing-style (CPS) translation. We demonstrate that a classical proof of a (Π_{2}^{0}) sentence Φ is a program which meets the specification Φ. We demonstrate that we can consistently give algorithmic content to the only constructively problematic rule of classical logic, the rule of double-negation elimination. This algorithmic content is the nonlocal control operator C (a relative of call-with-current-continuation). Moreover, we show that Friedman's translation is exactly a CPS-translation on the classical "program" (with C), converting it into a pure functional program (without C). Our work provides a semantic account of Friedman's translation, in terms of its effect on programs, making the connections (and the differences) between classical and constructive systems clearer and more precise. Moreover, we provide the first steps towards integrating nonlocal control operators into a type-theoretic explanation of computation.

title: Dependence Flow Graphs: An Algebraic Approach to Program Dependencies

abstract: The topic of intermediate languages for optimizing and parallelizing compilers has received much attention lately. In this paper, we argue that any good representation must have two crucial properties: first, the representation of a program must be a data structure that can be rapidly traversed to determine dependence information; second, the representation must be a program in its own right, with a parallel, local, model of execution. In this paper, we illustrate the importance of these points by examining algorithms for standard optimization-global constant propagation. We discuss the problems in working with current representations. Then, we propose a novel representation called the dependence flow graph which has each of the properties mentioned above. In this representation, dependencies are part of the computational mode, in that there is an algebra of operators over dependencies. We show that this representation leads to a simple algorithm, based on abstract interpretation, for solving the constant propagation problem. Our algorithm is simpler than, and as fast as, the best known algorithms for the problem. An interesting feature of our representation is that it naturally incorporates the best aspects of many other representations, including continuation-passing style, data and program dependence graphs, static single assignment form and dataflow program graphs.

title: Progress Measures and Finite Arguments for Infinite Computation
abstract: We establish principles for proving properties about infinite computations by reasoning about finite ones. We apply these principles to show that for a wide variety of verification problems - involving nondeterminism, fairness, and liveness - there are assertional verification methods that directly relate program and specification. Most previous research relies on transformations of programs in order to reduce a verification problem to problems that can be solved using classical techniques such a refinement mappings and well-founded orderings. Progress measures, the key innovation of this thesis, provide direct, syntax-independent verification techniques for a wide range of specifications. We exhibit progress measures for the language containment problem for nondeterministic automata; for verification with general fairness constraints; and for verification of very general specifications, including infinitary temporal logics. We obtain and optimal solution (in a recursion-theoretic sense) to the problem of verifying infinite computations by reasoning about finite ones. This result establishes a link between descriptive set theory and the theory of verification.

title: Random Reductions in the Boolean Hierarchy are Not Robust.
abstract: We investigate random reductions from complete sets in the Boolean Hierarchy to their complements. We show that under the assumption that the Polynomial Hierarchy is infinite, the error probability of such reductions cannot be significantly lower than a constant. This constant depends on the classes in question. Thus, random reductions in the Boolean Hierarchy are not robust. We also show that the trivial random reductions between classes at the second level of the Boolean Hierarchy are optimal.

title: Realizing Boolean Functions on Disjoint Sets of Variables
abstract: For switching functions f let $C(f)$ be the combinatorial complexity of f. We prove that for every $\varepsilon greater than 0$ there are arbitrarily complex functions $f:\{0,1\}^{n} \rightarrow \{0,1\}^{n}$ such that $C(fxf) \leq (1+ \varepsilon) C(f)$ and arbitrarily complex functions $g:\{0,1\}$ such that $C(v c(fxf)) \ leq (1 + \varepsilon)C(f)$. These results and the techniques developed to obtain them are used to show, that Ashenhurst decomposition of switching functions does not always yield optimal circuits and to prove a new result concerning the trade-off between circuit size and monotone circuit size.

title: A Note on Wavelet Bases for Two-Dimensional Surfaces
abstract: Recent work by Beylkin, Coifman and Rokhlin has demonstrated that integral equations for functions on IR can be solved rapidly by expressing the integrands in a wavelet basis. Boundary element methods for solving partial differential equations in three dimension rely on integral equations for functions defined on surfaces embedded in IR^{3}. Accordingly, it is of interest to extend the wavelet work to functions defined on surfaces. In this report, we define a basis of piecewise constant functions on surfaces in IR^{3} with properties akin to a wavelet basis. The basis we define is not useful for numerical computation because piecewise constant functions have poor approximation properties, but this work suggests an approach to define smoother wavelet bases for surfaces.

title: Flexible Text Matching for Information Retrieval
abstract: Very large text databases now exist in machine-readable form, covering arbitrary subject matter in unrestricted discourse areas. The conventional text retrieval approaches are not easily used in such circumstances, because the knowledge needed to understand unrestricted subject matter is not readily available for practical use. A new approach is outlined for text structuring and retrieval, based on flexible text matching methods using different context granularities. When global as well as local similarities exist between distinct texts, the presumption is that the texts cover semantically similar subject areas. This leads to the automatic introduction of links between related texts, and to the retrieval of text excerpts in response to available user queries. Evaluation results are given to demonstrate the effectiveness of the text matching approach.

title: The Molecule Problem: Determining Conformation from Pairwise Distances

abstract: The molecule problem is that of determining the coordinates of a set of points in space from a (usually sparse) set of pairwise distance measurements. As its name implies, it has applications in the determination of molecular conformation. Unfortunately, the molecule problem is NP-hard. We present an approach to the molecule problem that uses a very specialized divide-and-conquer technique. Instead of solving a single large problem we try to solve a sequence of smaller, presumably easier ones. These small problems consist of subsets of points whose relative locations can be determined uniquely. Once such a subset is positioned, its points can collectively be treated as a rigid body. This can greatly reduce the number of degrees of freedom in the problem. Identifying subsets of points whose relative locations can be uniquely determined requires exploiting some very special structure inherent in the molecule problem. We reduce this identification to a purely combinatoric characterization that ignores the actual distances. We develop necessary graph theoretic conditions for a set of points to have a unique solution, along with efficient algorithms to find subgraphs with these properties. These characterizations and algorithms combine ideas from matching theory, differential topology and matrix computations. These ideas have been implemented in ABBIE, a program to solve three-dimensional instances of the molecule problem. ABBIE combines the recursive decomposition described above with a nonlinear global optimizer to perform the coordinate determinations. Detail of this implementation are described, and numerical results of simulated chemical data are presented.

title: Tools for Constructing Distributed Reactive Systems
abstract: Many distributed applications can be cast as reactive systems, where a reactive system consists of an instrumented program that is monitored and controlled by an input-driven control program. Examples of non-real-time reactive systems include monitoring and debugging systems, tool integration services, and network and distributed application managers. There is currently little support for building reactive systems. This paper describes the Meta toolkit that provides such support. Using Meta, a distributed system can be instrumented with a sensor and actuator abstraction that exposes the state of the system for purposes of control. Then, a control program can be written that interacts with the instrumented system using guarded commands. Of particular concern is the efficiency of control, so Meta allows the control program to be distributed in order to take advantage of locality as much as possible.

title: Solving Nonlinear Matrix Equations on a Hypercube
abstract: Nonlinear matrix equations arise frequently in applied probability, especially in the numerical solution of many stochastic models in queueing, inventory, communications, and dam theories. Due to the huge amount of computations involved in these nonlinear matrix equations, the existing algorithms for the solutions have not been satisfactory. With the advent of parallel computers, the door is open for efficient parallel algorithms to tackle the problem. This paper is an effort in this direction. A parallel algorithm on distributed computer systems is devised, and numerical experiment is done on the hypercube.

title: Realizability and Kripke Forcing
abstract: Realizability, developed by Stephen Kleene, is a type-free device for extracting computations from logical specifications. Realizability analyzes the computational content of reasoning: it models the universe of recursive mathematics. Kripke and associated Categorical interpretations give a broader, topological/ algebraic semantics for constructive reasoning which is complete for intuitionistic logic. They are, therefore, a powerful and indispensable tool for modelling computationally meaningful formal systems. How are the two semantical paradigms related ? In this paper, we construct several Kripke and Categorical Models which are elementarily equivalent to Syntactic Realizability. By merging the two approaches we provide a new class of models and a framework for reasoning about computational evidence and the process of term extraction itself.

title: Concepts and Conditions for Confinement
abstract: THe confinement problem is concerned with preventing a computaitonal service from divulging information entrusted to it. A model of computer protection is presented and used to formally define the problem and its relation to protection mechanisms. Two types of confinement, one concerned with preventing the direct sending of messages and the other with also preventing the use of covert channels, are explored. For both types, conditions sufficient to insure confinement in terms of the capabilities of computations are presented. The conditions make it possible to identify exactly those objects, if any, which can serve as potential channels. Means for plugging the potential channels are also discussed.

title: A Note on Term Weighting and Text Matching
abstract: In information retrieval, it is not uncommon to be faced with large collections of unrestricted natural-language text. In such circumstances, the text analysis and retrieval operations must be based mainly on a study of the text collections actually under construction. Two main operations are of interest: a text analysis operation designed to assign content identifiers to the stored texts, and a text comparison system designed to identify texts covering particular subject areas. In the present note, some details are given concerning the usefulness of term weighting systems for the content analysis of natural-language texts, and of text matching strategies designed to identify relevant text items in answer to available search requests. A sample collection of electronic mail messages is used for experimental purposes.

title: Language Learning without Overgeneralization
abstract: Language learnability is investigated in the Gold paradigm of inductive inference from positive data. Angluin gave a characterization of learnable families in this framework. Here, learnability of families of recursive languages is studied when the learner obeys certain natural constraints. Exactly learnable families are characterized for prudent learners with the following types of constraints: (0) conservative, (1) conservative and consistent, (2) conservative and responsive, and (3) conservative, consistent, and responsive. The class of learnable families is shown to strictly increase going from (3) to (2) and from (2) to (1), while it stays the same going from (1) to (0). It is also shown that, when exactness is not required, prudence, consistency and responsiveness, even together, do not restrict the power of conservative learners.

title: Density Graphs and Separators
abstract: We propose a class of graphs that would occur naturally in finite-element problems, and we prove a bound on separators for this class of graphs. For three-dimensional graphs, our separator bound is $O(N^{2/3})$. We also propose a simple randomized algorithm to find this separator in $O(N)$ time. Such an algorithm would be used as a preprocessing step for the domain decomposition method of efficiently solving a finite-element problem on a parallel computer. This paper generalizes "local graphs" of Vavasis [1990] to the case of graphs with varying densities of nodes. It also generalizes aspects of Miller and Thurston's [1990] "stable graphs."

title: Efficiently Using Invariant Theory and Grouping Information for Model-Based Matching
abstract: This paper presents a method for efficiently maintaining and searching a database of three-dimensional models so they can be reliable recognized from arbitrary two-dimensional projections in the presence of noise and occlusion. The core of the process is the topologically-defined network of invariants which breaks three-dimensional models down into small, local groups of features and indexes these groups using translation, rotation, scaling, and orthographic projection invariant functions. The network encodes the geometrical relationships between these groups so that grouping information can be used to increase the speed of matching.

title: Improving Known Solutions is Hard
abstract: In this paper, we study the complexity of computing better solutions to optimization problems given other solutions. This is done in the context of the counterexample computation model introduced in [KPS90]. Assuming $PH \neq \sum^{P}_{3}$, we prove that PTIME transducers cannot compute optimal solutions for many problems, even given $O(n^{1-\epsilon})$ non-trivial solutions. These results are used to establish sharp lower bounds for several problems in the counterexample model. We extend the model by defining probabilistic counterexample computations and show that our results hold even in the presence of randomness.

title: Relations Between Diagonalization, Proof Systems, and Complexity Gaps
abstract: In this paper we study diagonal processes over time-bounded computations of one-tape Turing machines by diagonalizing only over those machines for which there exist formal proofs that they operate in the given time bound. This replaces the traditional "clock" in resource bounded diagonalization by formal proofs about running times and establishes close relations between properties of proof systems and existence of sharp time bounds for one-tape Turing machine complexity classes. Furthermore, these diagonalization methods show that the Gap Theorem for resource bounded computations does not hold for complexity classes consisting only of languages accepted by Turing machines for which it can be formally proven that they run in the required time bound.

title: Global Convergence of Damped Newton's Method for Nonsmooth Equations, via the Path Search
abstract: A natural damping of Newton's method for nonsmooth equations is presented. This damping, via the path search instead of the traditional line search, enlarges the domain of convergence of Newton's method and therefore is said to be globally convergent. Convergence behavior is like that of line search damped Newton's method for smooth equations, including Q-quadratic convergence rates under appropriate conditions. Applications of the path search include damping Robinson-Newton's method for nonsmooth normal equations corresponding to nonlinear complementarity problems and variational inequalities, hence damping both Wilson's method (sequential quadratic programming) for nonlinear programming and Josephy-Newton's method for generalized equations. Computational examples from nonlinear programming are given.

title: Proving Polynomial-Time for Sphere-Constrained Quadratic Programming
abstract: Recently Ye and Karmarkar have proposed similar algorithms for minimizing a nonconvex quadratic function on a sphere. These algorithms are based on trust-region work going back to Levenberg and Marquardt. Although both authors state that their algorithm is polynomial time, neither makes estimates necessary to prove that conclusion in a formal sense. In this report we derive estimates for the convergence of the algorithm. Our estimates are based on bounds for separation of roots of polynomials. These bounds prove that the underlying decision problem is polynomial time in the Turing machine sense.

title: On Computing the Homology Type of a Triangulation
abstract: We analyze an algorithm for computing the homology type of a triangulation. By triangulation, we mean a finite simplicial complex; its homology type is given by its homology groups (with integer coefficients). The algorithm could be used in computer-aided design to tell whether two finite-element meshes or Bezier-spline surfaces are of the same "topological type," and whether they can be embedded in $\Re^{3}$. Homology computation is a purely combinatorial problem of considerable intrinsic interest. While the worst-case bounds we obtain for this algorithm are poor, we argue that many triangulations (in general) and virtually all triangulations in design are very "sparse," in a sense we make precise. We formalize this sparseness measure, and perform a probabilistic analysis of the sparse case to show that the expected running time of the algorithm is roughly quadratic in the geometric complexity (number of simplices) and linear in the dimension.

title: A Relationship between Difference Hierarchies and Relativized Polynomial Hierarchies.
abstract: Chang and Kadin have shown that if the difference hierarchy over NP collapses to level k, then the polynomial hierarchy (PH) is equal to the kth level of the difference hierarchy over Σ_{2}^{p}. We simplify their proof and obtain a slightly stronger conclusion: If the difference hierarchy over NP collapses to level k, then PH = $\left(P_{(k-1)-tt}^{NP}\right)^{NP}$. We also extend the result to classes other than NP: For any class C that has $\leq_{m}^{p}$-complete sets and is closed under $\leq_{conj}^{p}$- and $\leq_{m}^{NP}$-reductions, if the difference hierarchy over C collapses to level k, then $PH^{C} = $\left(P_{(k-1)-tt}^{NP}\right)^{C}$. Then we show that the exact counting class $C_{=}P$ is closed under $\leq_{disj}^{p}$- and $\leq_{m}^{co-NP}$-reductions. Consequently, if the difference hierarchy over $C_{=}P$ collapses to level k then PH^{PP} is equal to $\left(P_{(k-1)-tt}^{NP}\right)^{PP}$. In contrast, the difference hierarchy over the closely related class PP is known to collapse. Finally, we consider two ways of relativizing the bounded query class P_{k-tt}^{NP}: the restricted relativization $P_{k-tt}^{NP^{C}}$, and the full relativization $\left(P_{k-tt}^{NP}\right)^{C}$. If C is NP-hard, then we show that the two relativizations are different unless PH^{C} collapses.

title: Programming with Process Groups: Group and Multicast Semantics

abstract: Process groups are a natural tool for distributed programming, and are increasingly important in distributed computing environments. However, there is little agreement on the most appropriate semantics for process group membership and group communication. These issues are of special importance in the Isis system, a toolkit for distributed programming. Isis supports several styles of process group, and a collection of group communication protocols spanning a range of atomicity and ordering properties. This flexibility makes Isis adaptable to a variety of applications, but is also a source of complexity that limits performance. This paper reports on a new architecture that arose from an effort to simplify Isis process group semantics. Our findings include a refined notion of how the clients of a group should be treated, what the properties of a multicast primitive should be when systems contain large numbers of overlapping groups, and a new construct called the causality domain. A system based on this architecture is now being implemented in collaboration with the Chorus and Mach projects.

title: The EIGHT Manual: A System for Geometric Modelling and Three-Dimensional Graphics on the Lisp Machine.
abstract: We describe a simple geometric modelling system called Eight which supports interactive creation, editing, and display of three-dimensional polyhedral solids. Perspective views of a polyhedral environment may be generated, and hidden surfaces removed. Eight proved useful for creating world models, and as an underlying system for modelling object interactions in robotics research and applications. It is documented here in order to make the facility available to others.

title: Tools for Monitoring and Controlling Distributed Applications.
abstract: The Meta system is a UNIX--based toolkit that assists in the construction of reliable reactive systems, such as distributed monitoring and debugging systems, tool integration systems and reliable distributed applications. Meta provides mechanisms for instrumenting a distributed application and the environment in which it executes, and Meta supplies a service that can be used to monitor and control such an instrumented application. The Meta toolkit is built on top of the ISIS toolkit; they can be used together in order to build fault-tolerant and adaptive distributed applications.

title: On the Semigroup of Strongly Connected Automata
abstract: In 1964 Weeg [6] has posed a question asking which semi-groups admit strongly connected automata. The presumed answer was given in 1971 by Oehmke [5] through the following statement: A semigroup admits strongly connected automaton if it has a homomorphic image either a nontrivial finite group or semigroup of the transformations of some right zero semigroup. This theorem can be reformulated as follows: A semigroup is a characteristic semigroup of strongly connected automaton if it has a homomorphic image either a nontrivial finite group or a semigroup of transformations of some right zero semigroup. In this paper the "only if" part of this theorem has been overthrown. Some related problems concerning strongly connectedness of finite automata are also investigated. Key Words and Phrases: semigroup, characteristic semigroup of an automaton, strongly connected automaton.

title: Tools for Constructing Distributive Reactive Systems
abstract: Many distributed applications can be cast as a reactive system, where a reactive system consists of an instrumented program that is monitored and/or controlled by an input-driven control program. Examples of non-real-time reactive systems include monitoring and debugging systems, tool integration services, and network and distributed application managers. There is currently little support for building reactive systems. This paper describes the Meta toolkit that provides such support. Using Meta, a distributed system can be instrumented with a sensor and actuator abstraction that exposes the state of the system for purposes of control. Then, a control program can be written that interacts with the instrumented system using guarded commands. Of particular concern is the efficiency of control, so Meta allows the control program to be distributed in order to take advantage of locality as much as possible.

title: Fast Ordered Multicasts
abstract: In this thesis, we present new protocols that provide reliable ordered multicasts to multiple overlapping process groups in the presence of failures. Our protocols provide two kinds of message delivery ordering - causal ordering and total ordering. Message delivery is also ordered with respect to the observation of group membership changes, a property known as virtual synchrony. Initially we examine solutions for the case of a single process group, and subsequently extend our solutions to encompass multiple overlapping process groups. In comparison with previous protocols for these problems, our protocols are cheaper and scale up better. An initial implementation of our protocols as part of the ISIS toolkit has produced encouraging performance results.

title: On the Complexity of Shattering Using Arrangements
abstract: A subdivision $\cal S$ of $\Re^{d}$ is said to shatter a set of objects if each object is contained within the closure of its own cell of $\cal S$. In this paper, we examine the problem of shattering a set of bounded polyhedral objects in $\Re^{d}$ by a subdivision formed by an arrangement of hyperplanes. We show for $\Re^{d}, d \geq$ 2 that finding a minimum-- cardinality set of hyperplanes whose arrangement shatters a set of points is NP-Complete. We then give algorithms to find a linear-size set of shattering hyperplanes for a set of n bounded polyhedral objects in $\Re^{d}$, if one exists. For $d=2$, we provide two algorithms with worst-case time complexities $O(E+N$log$N+n^{2}$log$n$) and $O(E+N$log$N+C$log$n+nC^{.695})$, where E is the size of the visibility graph of the objects, N is the total number of vertices, and C is the number of candidate lines considered (at worst min\{E,n^2\}). Our final algorithm has worst-case time complexity $O(N^{d+1})$ for $d \geq 3$.

title: A Note on Time-Space Bounded Interactive Protocols.
abstract: In this paper, we examine the power of time-space bounded interactive protocols with private coins. The class of languages having logspace, polynomial-time bounded private coin protocols is exactly PSPACE. We generalize this result to other time-space bounded protocols. As a consequence we obtasin that EXPSPACE is exactly the class of languages having polynomial-space, exponential-time bounded private coin interactive protocols. This coupled with earlier work by Condon, Fortnow and Lund gives us the following characterization of standard complexity classes in terms of time-space bounded interactive protocols.

title: Shattering Configurations of Points With Hyperplanes.
abstract: An arrangement of hyperplanes $\cal A$ in $\Re^d$ is said to shatter a point set $\cal O$ if each point of $\cal O$ is contained within the interior of its own cell of $\cal A$. In this paper, we investigate the number of hyperplanes required by an arrangement that shatters a set of n points in general position. We show that such sets can require between $\Omega(\sqrt[d]{n})$ and $\Omega(n)$ shattering hyperplanes. We also provide an algorithm that finds a linear-size shattering for such sets. The number of hyperplanes produced exceeds the requirements of the worst known example in $\Re^d$ by at most constant, which depends only on d. We also give some results for when the points are in general convex position.

title: Consistent Detection of Global Predicates

abstract: A fundamental problem in debugging and monitoring is detecting whether the state of system satisfies some predicate. If the system is distributed, then the resulting uncertainty in the state of the system makes such dectection, in general, ill-defined. This paper presents three algorithms for detecting global predicates in a well-defined way. These algorithms do so by interpreting predicates with respect to the communication that has occured in the system.

title: Rabin Measures and Their Applications to Fairness and Automata Theory
abstract: Rabin conditions are general class of properties of infinite sequences that emcompass most known automata-theoretic acceptance conditions and notions of fairness. In this paper we show how to determine whether a program satisfies a Rabin condition by reasoning about single transitions instead of infinite computations. We introduce a concept, called a Rabin measure, which in a precise sense expresses progress for each transition toward satisfaction of the Rabin condition. When applied to termination problems under fairness constraints, Rabin measures constitute a simpler verification method than previous approaches, which often are syntax-dependent and require recursive applications of proof rules to syntactically transformed programs. Rabin measures also generalize earlier automata-theoretic verification methods. Combined with a result by Safra, our result gives a method for proving that a program satisfies a nondeterministic Buchi automaton specification.

title: Improving Sampling and Reconstruction Techniques for Radiosity
abstract: The view-independent global illumination problem is rephrased as one determining a radiance function across each surface in the environment. A new methodology for diffuse environments, based on the sampling and reconstruction of these functions is introduced. Within this context, the following problems are investigated: (i) where the radiance functions should be samples; (ii) how to evaluate a radiance function at each sample; and (iii) how to reconstruct a radiance function for the set of samples. The new methodology relaxes some of the assumptions built into current radiosity algorithms. Results are presented which show that the new methodology yields significantly higher accuracy than existing radiosity methods.

title: Numerical Methods for Hypersingular and Near-Singular Boundary Integrals in Fracture Mechanics
abstract: The boundary integral equation is one of several equivalent forms of governing equations that can be used to compute approximate solutions to boundary value problems in elasticity and potential flow analysis. Since it determines the entire solution in terms of values only on the boundary, there are possible order-of-magnitude advantages in solution time and geometric complexity over better known `domain-based' methods such as finite elements and finite differences. In practice, it has been hard to capitalize on these advantages. Many of the difficulties center around inablility to perform certain numerical integrations. This thesis presents (a) a systematic `modal' method of converting singular integrals to easier integrals over `far' surfaces (b) an otimal quadrature method for the `nearly singular' integration problem. An existence

proof is given to show that all surface integrals arising from the 3D boundary integral can be converted to easier contour integrals if basis functions are constructed in a cartesian sense, rather than the common parametric formulations. Strokes vectors needed to make this result useful are demonstrated for the Laplace equation and for some cases elasticity. Comparison to analytic benchmark cases shows that the method produces accurate stress intensity factors for 3-dimensional fracture analysis.

title: Proving Nondeterministically Specified Safety Properties Using Progress Measures
abstract: Using the notion of progress measures, we discuss verification methods for proving that a program satisfies a property specified by an automaton having finite nondeterminism. Such automata can express any safety property. Previous methods, which can be derived from the method presented here, either rely on transforming the program or are not to complete. In contrast, our ND progress measures describe a homomorphism from the unaltered program to a canonical specification automaton and constitute a complete verification method. The canonical specification automaton is obtained from the classical subset construction and a new subset construction, called historization.

title: Minimum Norm Symmetric Quasi-Newton Updates Restricted to Subspaces
abstract: The Davidson-Fletcher-Powell and Broyden-Fletcher-Goldfarb-Shanno updates have been the two most successful quasi-Newton updates for a variety of applications. One reason offered in explanation is that they constitute, in an appropriate norm and metric, the minimum norm change to the matrix, or its inverse, being approximated which preserves symmetry and obeys the quasi-Newton equation. Recent methods have reason to consider updates restricted to certain subspaces. In this paper we derive the general minimum norm symmetric quasi-Newton updates restricted to such subspaces. In the same appropriate norm and metric, the minimum norm change update to the matrix or its inverse is shown to be, respectively, the rank-two update which is a particular projection of the DFP or BFGS onto this subspace.

title: Beyond Keyframing: An Algorithmic Approach to Animation

abstract: The recent explosion of interest in physical system simulation may soon lead to realistic animation of passive objects, such as sliding blocks or bouncing balls. However, complex active objects (like human figures and insects) need control mechanism to direct their movements. We present a paradigm that combines the advantages of physical simulation and algorithmic specification of movement. The animator writes an algorithm to control the object and run this algorithm on physical simulator to produce the animation. Algorithms can be reused or combined to produce complex sequences of movement , eliminating the need for tedious keyframing. We have applied this paradigm to control a walking biped. The walking algorithm is presented along with the results from testing with Newton simulation system.

title: Robust Point Location in Approximate Polygons
abstract: This paper presents a framework for reasoning about robust geometric algorithms. Robustness is formally defined and a data structure called an approximate polygon is introduced and used to reason about polygons constructed of edges whose positions are uncertain. A robust algorithm for point location in an approximate polygon is presented. The algorithm uses only the signature of the point (not its location) to determine whether the point is inside or outside the polygon. An approximate polygon could, by shifting its edges back and forth within their error bounds, induce a large number of different line arrangements. The cell C_{a} with signature α in one such arrangement will be different than the cell ${C'}_{a}$ with signature α in another arrangement. This paper proves that, regardless of their position and shapes, the cells C_{a} and ${C'}_{a}$ are always to the same side of the polygons which induce their respective arrangements.

title: On the Complexity of ML Typability with Overloading
abstract: We examine the complexity of type checking in an ML-style type system that permits functions to be overloaded with different types. In particular, we consider the extension of the ML Type system proposed by Wadler and Blott in the appendix of [WB89], with global overloading only, that is, where the only overloading is that which exists in an initial type assumption set; no local overloading via over and inst expressions is allowed. It is shown that under a correct notion of well-typed terms, the problem of determining whether a term is well typed with respect to an assumption set in this system is undecidable. We then investigate limiting recursion in assumption sets, the source of the undecidability. Barring mutual recursion is considered, but this proves too weak, for the problem remains undecidable. Then we consider a limited form of recursion called parametric recursion. We show that although the problem becomes

decidable under parametric recursion, it appears harder than conventional ML typability, which is complete for DEXPTIME [Mai90].

title: The Effectiveness of the Thesaurus Method in Automatic Information Retrieval
abstract: Term grouping and thesaurus methods have frequently been incorporated into automatic content analysis programs as devices for the recognition of synonymous expressions and of linguistic entities that may be semantically similar but syntactically distinct. While it has frequently been asserted that the recognition of synonyms is essential in language analysis, actual proofs of the usefulness of a thesaurus in automatic information retrieval are outstanding. In the present study, formal proofs are given of the effectiveness under well-defined conditions of the thesaurus method in information retrieval. It is shown, in particular, that when certain semantically related terms are added to the information queries originally submitted by the user population, a superior retrieval system is obtained in the sense that for every level of the recall the retrieval precision is at least as good for the altered queries as for the original ones.

title: A Globally Convergent Method for Lp Problems
abstract: The l_p norm discrete estimation problem $min_{x \epsilon \Re}{n}$ $\|b-A^{T}x\|_{p}$ is troblesome when p is close to unity because the objective function approaches a discontinuous form. In this paper, we present an efficient approach for solving l_p norm problems for all $1\leq p less than 2$. When $p=1$, it is essentially the method presented in [4], which is globally and quadratically convergent algorithm under some nondegeneracy assumptions. The existing iteratively reweighted least squares (IRLS) can be obtained from the new approach by updating some "dual multipliers" in a special fashion. The new method is globally convergent. It is superlinearly convergent when there is no zero residual at the solution. The main computational cost of our new methos is the same as the IRLS method: a reweighted least squares solve. Numerical experiments indicate this method is significantly faster than popular iteratively reweighted least squares method when p is close or equal to one.

title: An Evaluation Semantics for Classical Proofs
abstract: We show how to interpret classical proofs as programs in a way that agrees with the well-known treatment of constructive proofs as programs and moreover extends it to give a computational meaning to proofs claiming the existence of a value satisfying a recursive predicate. Our method turns out to be equivalent to H. Friedman's proof by "A-translation" of the conservative extention of classical over constructive arithmetic for Π^{0}_{2} sentences. We show that Friedman's result is a proof-theoretic version of a semantics-preserving CPS-translation from a nonfunctional programming language (with the "control" (C, a relative of call/cc) operator) back to a functional programming language. We present a sound evaluation semantics for proofs in classical number theory (PA) of such sentences, as a modification the standard semantics for proofs in constructive number theory (HA). Our results soundly extend the proofs-as-programs paradigm

to classical logics and to programs with C.

title: Symoblic/Numeric Techniques in Modeling and Simulation
abstract: Modeling and simulating collections of physical objects which are subject to a wide variety of physical forces and interactions is exceedingly difficult. The construction of a single simulator capable of dealing with all possible physical processes is completely impractical and, it seems to us, wrong-headed. Instead, we propose to build custom simulators for single, particular collections of physical objects and where pre-specified physical phenomena are involved. For such an approach to be practical, an environment needs to be provided that facilitates the quick construction of these simulators. In this paper we describe the essential features of such an environment and describe in some detail how a general implementation of the weight residual method, one of the more general classes of numerical integration techniques, can be used.

title: Classical Proofs as Programs: How, What and Why
abstract: We recapitulate Friedman's conservative extension result of(suitable) classical over constructive systems for Π_{2}^{0}sentences, viewing it in two lights: as a translation of programs from an almost-functional language (with $\cal C$) back to its functional core, and as a translation of a constructive logic for a functional language to a classical logic for an almost-functional language. We investigate the computational properties of the translation and of classical proofs and characterize the classical proofs which give constructions in concrete, computational terms, rather than logical terms. We characterize different versions of Friedman's translation as translating slightly different almost-functional languages to a functional language, thus giving a general method for arriving at a sound reduction semantics for an almost-functional language with a mixture of eager and lazy constructors and destructors, as well as integers, pairs, unions, etc. Finally, we describe how to use classical reasoning in a disciplined manner in giving classical (yet constructivizable) proofs of sentences of greater complexity than Π_{2}^{0}. This direction offers the possibility of applying classical reasoning to more general programming problems.

title: On Parallelism in Turing Machines
abstract: A model of parallel computation based on a generalization of nondeterminism in Turing machines is introduced. Complexity classes //T(n)-TIME, //L(n)-SPACE, //LOGSPACE, //PTIME, etc. are defined for these machines in a way analogous to T(n)-TIME, L(n)-SPACE, LOGSPACE, PTIME, etc. for deterministic machines. It is shown that, given appropriate honesty conditions, 217z L(n)-SPACE $\subseteq$ //L$(n)^{2}$-TIME T(n)-TIME $\subseteq$ //log T(n)-SPACE //L(n)-SPACE $\subseteq$ exp L(n)-TIME //T(n)-TIME $\subseteq$ T$(n)^{2}$-SPACE thus //EXPTIME = EXPSPACE //PSPACE = EXPTIME //PTIME = PSPACE //LOGSPACE = PTIME ? = LOGSPACE That is, the deterministic hierarchy LOGSPACE $\subseteq$ PTIME $\subseteq$ PSPACE $\subseteq$ EXPTIME $\subseteq \ldots$ shifts by exactly one level when parallelism is introduced. We give a natural characterization of the polynomial time hierarchy of Stockmeyer and Meyer

in terms of parallel machines. Analogous space hierarchies are defined and explored, and a generalization of Savitch's result NONDET-L(n)-SPACE $\subseteq$ L$(n)^{2}$-SPACE is given. Parallel finite automata are defined, and it is shown that, although they accept only regular sets, in general, $2^{2^{k}}$ states are necessary and sufficient to simulate a k-state parallel finite automaton deterministically.

title: When Is Partial Trace Equivalence Adequate?
abstract: Two processes are partial trace equivalent if they can perform the same sequences of actions in isolation. Partial trace equivalence is perhaps the simplest possible notion of process equivalence. In general, it is too simple: it is not usually an adequate semantics. We investigate the circumstances under which it is adequate, which are surprisingly rich. We give two substantial classes of language for which partial traces are adequate. In one class, partial trace equivalence suffices for total correctness, and operations such as true sequencing are possible: but all processes are determinate and silent moves are not possible. The other class admits indeterminacy and silent moves, but partial traces only suffice for partial correctness and true sequencing is not definable.

title: Theory of R-functions and Applications: A Primer
abstract: An R-function is real-valued function characterized by some property that is completely determined by the corresponding property of its arguments, e.g., the sign of some real functions is completely determined by the sign of their arguments. More generally, such a property could be determined by some partition of the real axis. If the axis is partitioned into k subsets, each R-function corresponds to a companion function of k-valued logic. This relationship allows one to represent a logical predicate of n variable by a real-valued function of n arguments. The latter can be evaluated, differentiated, and possesses many other interesting properties. V.L. Rvachev first suggested R-functions in l963. Since then, he and his colleagues have significantly developed the theory and found many applications. Their work is described in numerous books and articles, unfortunately mostly in Russian. A complete list of references through l987 can be found in [Shi88]. An important application of R-functions is in the description of geometric objects. Any object defined by a predicate on "primitive" geometric regions (e.g. regions defined by a system of inequalities) can now be represented by a single inequality, or equation. Furthermore, these real-valued functions can be constructed so that they have certain useful logic and differential properties. Application of theory of R-functions could have a profound effect on many problems where geometric information can

be accounted for analytically. For example, according to [Rva82], R-functions have found applications in many unexpected areas, such as study of stability of motion, medical diagnostics, and chemical engineering, in addition to those described in this report. This primer summarizes some basic results from the theory of R-functions and decribes (rather superficially) some of the applications studied in the Soviet Union. As far as I know, this is the first such introduction to R-functions in English. Its main purpose is to stimulate interest in R-functions in the research community; it is not intended to serve as a comprehensive reference. While this document contains no original results, absorbing, translating, interpreting, and condensing the contents of the references did require a substantial judgement on my part. The original sources offer a wealth of additional material that was omitted for the sake of simplicity and coherence of this document. Thus, I also accept the responsibility for all mistakes, misinterpretations, and omissions in this report. While the main applications of R-functions have been in the description of geometric objects, the developed theory does not seem to rely on many known results in combinatorial, algebraic, and computational geometry and topology. In an effort to preserve the spirit of the original work, I resisted making "improvements" in the presentation.

title: Abstract Semantics for a Higher order Functional Language with Logic Variables
abstract: The addition of logic variables to functional languages gives the programmer novel and powerful tools such as incremental definition of data structures through constraint intersection. A number of such "hybrid" languages, like FGL + LV [11], Id [17] and Qute [24], have been implemented and are in active use. Pure functional and logic programming languages can be given elegant abstract semantics as functions and relations over values. The definition of such an abstract semantics for a functional language with logic variables has remained an open problem. In an earlier paper, we gave such a semantics for the special case of a first-order functional languages with logic variables by reducing the problem to that of solving simultaneous fixpoint equations involving closure operators over a Scott domain [9]. In fact, we obtained the rather strong result that the denotational semantics was fully abstract with respect to the operational semantics. However, the problem for higher-order languages remain open, in part because higher-order functions can interact with logic variables in complicated ways to give rise to behavior reminiscent of own variables in Algol-60. This problem is solved completely in this paper. We show that in the presence of logic variables, higher-order functions may be modeled extensionally as closure operators on graphs ordered a way reminiscent of the ordering on extensible records in studies of inheritance [1]. We then extend the equation solving semantics of the first-order subset to the full language, and prove the usual soundness and adequacy theorems for this semantics. These results show that a higher-order functional language with logic variables can be viewed as a language of incremental definition of functions.

title: Generation and Search of Clustered Files
abstract: A classified, or clustered file is one where related, or similar records are grouped into classes, or clusters of items in such a way that all items within a cluster are jointly retrievable. Clustered files exhibit substantial advantages in many retrieval environments over the more conventional inverted list or multilist technologies. An inexpensive file clustering method applicable to large files is given together with appropriate file search methods. An abstract model is used to predict the retrieval effectiveness of various search methods

in a clustered file environment, and experimental evidence is introduced to confirm the usefulness of the model. As an example, a collection of research papers in computer science is clustered automatically, and the resulting research clusters are compared with exissting, manually constructed taxonomies for the computer field.

title: Boundry-Based Separation for B-rep $\rightarrow$ CSG Conversion
abstract: We have shown earlier that one of the most difficult steps in performing b-rep $\rightarrow$ CSG conversion for a curved solid object consists of determining a set of halfspaces that is sufficient for a CSG representation of the solid. This usually requires the construction of additional halfspaces whose boundaries do not contribute to the boundary of the solid. Such halfspaces are called separating halfspaces because their purpose is to separate certain subsets of E^{3} inside the solid from those outside of the solid. Construction of separating halfspaces is specific to a particular geometric domain, but several generic approaches are possible. A boundary-based separation is a construction of separating halfspaces that relies on the information present in the boundary of the solid being converted While boundary-based separation for solids with non-planar edges is not well understood, we study the contraints on the degree of separating halfspaces, and show that a set of linear separating halfspaces exists for any solid whose boundary contains only planar edges. We apply the boundary-based separation to solids bounded by general quadric surfaces. Specifically, we prove that a sufficient set of linear separating halfspaces exists for any such solid, and consider the required constructions in several common situations. Implications for more general solids are also discussed.

title: Trade-offs in True Concurrency: Pomsets and Mazurkiewicz Traces
abstract: We compare finite pomsets and Mazurkiewicz traces, two models of true concurrency which generalize strings. We show that Mazurkiewicz traces are equivalent to a restricted class of pomsets. The restrictions lead to extra structure, with results analogous to the differences between simply typed and untyped languages. For example, traces are consistently complete in the prefix order, while pomsets are not; also, traces can be distinguished by observing sequences of actions, in contrast to the elaborate scheme required for distinguishing pomsets. Finally, we discuss the operations of sequential and parallel composition in the two models. This is part of an ongoing effort to relate models of concurrency.

title: Modeling Arbitrary Smooth Objects with Algebraic Surfaces
abstract: Representing, manipulating, and reasoning about physical objects is a central area of research in a wide range of applications, including solid modeling, computeraided design, computer graphics, and robotics. In these applications, complex physical objects are modeled using free-form surfaces, surfaces that are smooth but otherwise arbitrary. Traditionally, free-form surfaces are constructed from parametric patches, which are very successful as far as design and rendering are concerned. However, manipulating and reasoning about physical objects with parametric patches poses fundamental difficulties. For example, the difficulty of evaluating and respresenting the intersection of parametric patches has hindered the development of solid modeling systems based on parametric patches alone. This thesis addresses the problem of constructing free-form surfaces using low degree implicit patches, which facilitate manipulating and reasoning about physical objects. We establish the fact that quadric patches and cubic patches are flexible enough for free-form surface constructions: (i) given an arbitrary polyhedron, we show how to fit a smooth piecewise quadric surface through the vertices of the polyhedron without splitting its facets; (ii) given an arbitrary polyhedron with arbitrarily prescribed tangent planes at its vertices, we present an algorithm that fits a smooth piecewise cubic surface through the vertices of the polyhedron so that the surface is tangent to the prescribed tangent plane at each vertex. In constructing free-form surfaces, we also study three related issues. First, we examine the power and limitations of blending techniques. We show that on the one hand, blending techniques can be used to improve the efficiency of free-form surface constructions; on the other, blending techniques have their fundamental limitations. Second, we provide a complete understanding of the weight functions for quadric surfaces meeting with geometric continuity. Finally, we tackle some shape control issues of implicit patches. In particular, we demonstrate how to achieve the convexity of a quadric or cubic patch by manipulating its control points.

title: The Information Revolution - Myth or Reality
abstract: The early work in the design of automatic information systems, exemplified by the contributions of H. P. Luhn and others, now goes back nearly twenty years. It may be useful to ask whether a great deal has changed in these twenty years, and if so, what contributions have been most influential and indicative of future trends. Two contradictory opinions are often heard: the optimists speak of the information revolution and think of mechanized international information networks; the pessimists, on the other hand, assert that little has changed and point to the continued use for well over twenty years of substantially unchanged file organizations, indexing systems, and search techniques. An attempt is made to separate fact from fiction by describing where we have stood still, and where progress has occurred. In particular, the technological environment which has evolved in many directions is distinguished from most of the intellectual components of information retrieval which have remained unchanged. Suggestions are also made relating to the design

and operations of future automatic information systems.

title: The Theory and Pratice of Robust Geometric Computation, or, How toBuild Robust Solid Modelers
abstract: The field of solid modeling makes extensive use of a variety of geometric algorithms. When implemented on a computer, these algorithms often fail because the computer only provides floating point arithmetic, while the agorithms are expecting infinite precision arthmetic on real numbers. These algorithms are not robust. This dissertation presents a theory of robustness. With this theory, a robust point location algorithm is developed. This algorithm determines whether a point lies inside a polygon, where both the point and the polygon are represented approximately. The elegant theoretical approach to robustness is not viable in practice: algorithms like those used in solid modeling are generally too complex for this approach. This dissertation presents a practical alternative to the formal theory of robustness; this alternative is called local robustness. Local robustness is applied to the design of a polyhedral intersection algorithm, which is an important component in many solid modelers. The intersection algorithm has been implemented, and, in extensive tests, has never failed to produce a valid polyhedron of intersection. A concise characterization of the locally robust intersection algorithm is presented; this characterization can be used to develop variants of the intersection algorithm, and to develop robust versions of other solid modeling algorithms.

title: Polymorphic Type Inference for Languages with Overloading and Subtyping
abstract: Many computer programs have the property that they work correctly on a variety of types of input; such programs are called polymorphic. Polymorphic type systems support polymorphism by allowing programs to be given multiple types. In this way, programs are permitted greater flexibility of use, while still receiving the benefits of strong typing. One especially successful polymorphic type system is the system of Hindley, Milner, and Damas, which is used in the programming language ML. This type system allows programs to be given universally quantified types as a means of expressing polymorphism. It has two especially nice properties. First, every well-typed program has a "best" type, called the principal type, that captures all the possible types of the program. Second, principal types can be inferred, allowing programs to be written without type declarations. However, two useful kinds of polymorphism cannot be expressed in this type system: overloading and subtyping. Overloading is the kind of polymorphism exhibited by

a function like addition, whose types cannot be captured by a single universally quantified type formula. Subtyping is the property that one type is contained in another, as, for example, $int \subseteq real$. This dissertation extends the Hindley/Milner/Damas type system to incorporate overloading and subtyping. The key device needed is constrained universal quantification, in which quantified variables are allowed only those instantiations, that satisfy a set of constraints. We present an inference algorithm and prove that it is sound and complete; hence it infers principal types. An issue that arises with constrained quantification is the satisfiability of constraint sets. We prove that it is undecidable whether a given constraint set is satisfiable; this difficulty leads us to impose restrictions on overloading. An interesting feature of type inference with subtyping is the necessity of simplifying the inferred types-the unsimplified types are unintelligible. The simplification process involves shape unification, graph algorithms such as strongly connected components and transitive reduction, and simplifications based on the monotonicities of type formulas.

title: Investigations Into Abstraction and Concurrency
abstract: Abstract semantics serves as an interface between a language and the user: the interface serving to hide a significant degree of operational detail and present a simpler view of program execution to the user. What are the properties that an abstract semantics should satisfy? It was an insight of Strachey [4l] that the abstract semantics must be compositional; thus, one must be able to "build up" the abstract meaning of a program from the abstract meanings of its components. Note that it is not immediately obvious how one thinks of recursive programs in this manner. This is the role of fixpoint theory developed by Scott [62]. Informally, fixpoint theory formalisms the intuitive inductive arguments that one uses in reasoning about recursive programs. The theory developed by Scott works for determinate programs: programs that yield one output for every input. Thus, the theory is inadequate to handle indeterminate programs: programs that can yield more than one output for a given input. Powerdomains, that can be viewed as the computable analogue of the powerset, were developed to enlarge the scope of the theory of Scott to handle indeterminate computations [52,64]. Domain theory, enriched with powerdomain constructions to handle indeterminacy has been successful in serving as a mathematical formalism powerful enough to specify abstract semantics for tranformational programs: programs that take a input, compute in isolation and return an output. Thus, programs are usually denoted by functions in the determinate case and as Input-Output relations in the indeterminate case. The semantics is termed abstract because it hides significant degree of internal operational detail and presents an extensional view of programs. The situation is not as clear for interactive programming systems: systems built out of processes which engage in communication with the environment and/or other processes while computing. The key difference from transformational systems is that the output produced by a process can influence its input. Static, determinate dataflow [32] is the prime example of the few models interactive systems that are amenable to extensional treatment.

title: Practical Utility of Knowledge-Based Analyses: Optimizations and Optimality for an Implementation of Asynchronous, Fail-Stop Processes (Extended Abstract).
abstract: The Group Membership Problem is concered with propagating changes in the membership of a group of processes to the members of that group. A restricted version of this problem allows one to implement a fail-stop failure model of processes in an asynchronous environment assuming a crash failure model. While the ISIS Toolkit relies on this for its Failure Detector, the current specification of GMP sheds no light on how to implement it. We present a knowledge-based formulation, cast as a commit-style problem, that is not only easier to understand, but also makes clear where optimizations to the ISIS implementation are and are not possible. In addition, the epistemic formulation allows us to use the elegant results of knowledge-acquisition theory to discover a lower bound on the required number of messages, construct a minimal protocol, and discuss the tradeoffs between the message-minimal protocol and the optimized ISIS implementation.

title: Computional Learning of Languages
abstract: This thesis focuses on the Gold model of inductive inference from positive data. There are several aspects in which the model appears unsatisfactory for language learning: the class of families of learnable languages is highly restricted; even if a family is learnable, there exists no uniform method to obtain a learner for it, and the learner itself is complex. In this thesis, some such criticisms are being addressed. It is shown that no automatic synthesis of a learner from the description of a learnable family is possible. Nevertheless, in some special cases, this synthesis can be achieved and a general result is developed. In order to make the learner simpler, it is stipulated that the learner can change its guess only when the guess is inconsistent with the input evidence. Such a conservative learner never overgeneralizes. Exactly learnable families are characterized for prudent learners with the following types of constraints: (0) conservative, (1) conservative and consistent, (2) conservative and responsive, and (3) conservative, consistent and responsive. It is also shown that, when exactness is not required, prudence, consistency and responsiveness, even together, do not restrict the power of conservative learners. Conservative learners are simple in only one respect; even though it is easy to determine when to make a new guess, it is still hard to know what this guess should be. Finally, a learner that exploits pattern evident in the input is developed. Absence of a particular string over a suitable interval of the input can be viewed as a kind of "indirect negative evidence". Now, the learning criterion needs to be weakened to allow limited failure. It is shown that any family of languages can be learned with probability 1 from stochastic input, provided something is known about the probability distribution according to which the input is presented. Given the family, the learner is uniformly constructible. Further, the behavior of the learner is simpler in many aspects. It is expected that a variety of other natural constraints can be imposed on this learner without additional cost.

title: Metalogical Frameworks
abstract: In computer science we speak of implementing a logic; this done in a programming language, such as Lisp, called here the implementation language. We also reason about the logic, as in understanding how to search for proofs or in knowing it is consistent; in the terminology of mathematical logic, these arguments are conducted in the metalanguage of the object language being implemented. We also reason about the implementation itself, say to know it is correct. This is done in a programming logic. How do all these logics relate? This paper considers that question and more. We show that by taking the view that the metalogic is primary, these other parts are related in standard ways. The metalogic must be suitably rich so that the object logic can be presented as an abstract data type, and it must be suitably computational (or constructive) so that an instance of that type is an implementation. The data type abstractly encodes all that is relevant for metareasoning, i.e. not only the term constructing functions but also the principles for reasoning about arbitrary terms and computing with them. Our work can also be seen as an approach to the task of finding a generic way to present logics and their implementations, which is for example the goal of the Edinburgh Logical Frameworks (ELF) effort. This approach extends well beyond proof-construction and includes computational metatheory as well.

title: Deterministic On-Line Routing on Area-Universal Networks
abstract: Two deterministic routing networks are presented: the pruned butterfly and the sorting fattree. Both networks are area-universal, i.e., they can simulate any other routing network fitting in similar area with polylogarithmic slowdown. Previous area-universal networks were either for the off-line problem, where the message set to be routed is known in advance and substantial precomputation is permitted, or involved randomization, yielding results that hold only with high probability. The two networks introduced here are the first that are simultaneously deterministic and on-line, and they use two substantially different routing techniques. The performance of their routing algorithms depends on the difficulty of the problem instance, which is measured by a quantity λ known as the load factor. The pruned butterfly algorithm runs in time O(λ log^{2} N), where N is the number of possible sources and detinations for messages and λ is assumed to be poylnomial in N. The sorting fat-tree algorithm runs in O ($\ lambda$ log N + log^{2} N) time for a restricted class of message sets including partial permutations. Other results of this work include a new type of sorting circuit and an area-time lower bound for routers.

title: Maintaining Consistency in Distributed Systems
abstract: How should distributed systems preserve consistency in the presence of concurrency and failures? For systems designed as assemblies of independently developed components, concurrent access to data or data structures would normally arise within individual programs, and be controlled using mutual exclusion constructs, such as semaphores and monitors. Where data is persistent and/or sets of operations are related to one another, transactions or linearizability may be more appropriate. Systems that incorporate cooperative styles of distributed execution often replicate or distribute data within groups of components. In these cases, group-oriented consistency properties must be maintained, and tools based on the virtual synchrony execution model greatly simplify the task confronting an application developer. All three styles of distributed computing are likely to be seen in future systems - often, within the same application. This leads us to propose an integrated approach that permits applications that use virtual synchrony to with concurrent objects that respect a linearizability constraint, and vice versa. Transactional subsystems are treated as a special case of linearizability. Keywords and phrases: Transaction, atomicity, monitors, serializability, linearizability, virtual synchrony, object-oriented programming, distributed computing, federated databases, fault-tolerance.

title: Covering a Triangle with Disks Centered on its Boundary
abstract: Let $\cal P$ be a triangle and $\cal D_{1}, \cal D_{2}$ be disks centered on the boundary of $\cal P$ with radii r_{1}, $r}_{2}$. The disks are chosen so that $\cal D_{1}$ $\cup$ $\cal D$$_{2}$ covers $\cal P$ and r_{1} + r_{2} is minimized. We show that an optimal covering must exist with r_{2} = 0. In such a single disk covering, $\cal D_{1}$ is always located on the longest side of $\cal P$. The exact location and and size depend on the angles of $\cal P$; we provide a complete characterization and then generalize it to convex polygons. We show that the minimum covering disk can be determined in $\cal O (n)$ time for a convex polygon with n sides. However, it is open for $n \geq$ 4 whether there is always a single disk covering that is optimal.

title: Incremental Reduction in the Lambda Calculus and Related Reduction Systems
abstract: An incremental algorithm is one that computes a function repeatedly on a series of inputs that differ only slightly from one another, yet avoids unnecessary duplication of computations from one input to the next. This thesis is a study of incremental computation in a general class of reduction systems, focusing particularly on the untyped lambda calculus and term rewriting systems. We also study implementation techniques used for such reduction systems and the question of the existence of optimal reduction strategies. Most of our results are based on a new class of reduction systems we define called regular replacement systems. These systems combine an abstract reduction relation with a notion of structure defined by a Brouwerian algebra. The reduction relation defines a computation system, while the algebra is used to define what constitutes an incremental change to some object. Numerous reduction systems, including many term and graph rewriting systems and a variant of the lambda calculus, constitute regular replacement systems. Among our results is a generalization of the lattice-theoretic reduction theory of Levy to regular replacement systems. This theory makes it possible to give a precise and intuitively appealing definition of what it means for both incremental and non-incremental computations to be optimal. We then investigate a family of term rewriting systems centered around a system we call $\bf \Lambda${\bf CCL}. Each of these systems is capable of simulating a normalizing reduction strategy in the lambda calculus. However, unlike the lambda calculus, the notion of substitution is an explicit part of $\bf \Lambda${\bf CCL}'s semantics, rather than being relegated to the status of meta-theory. Our study culminates with the definition of a $\bf \Lambda${\bf CCL}-based incremental reduction algorithm. This algorithm is optimal, yet it is simple enough to allow a practical implementation. We believe that appropriate generalizations of the ideas embodied in the algorithm can be used in a variety of practical settings, particularly those in which an algorithm is expressed in a functional or applicative manner.

title: On The Structure Of NP Computations Under Boolean Operators
abstract: This thesis is mainly concerned with the structural complexity of the Boolean Hierarchy. The Boolean Hierarchy is composed of complexity classes constructed using Boolean operators on NP computations. The

thesis begins with a description of the role of the Boolean Hierarchy in the classification of the complexity of NP optimization problems. From there, the thesis goes on to motivate the basic definitions and properties of the Boolean Hierarchy. Then, these properties are shown to depend only on the closure of NP under the Boolean operators, AND$_{2}$ and OR$_{2}$. A central theme of this thesis is the development of the hard/easy argument which shows intricate connections between the Boolean Hierarchy and the Polynomial Hierarchy. The hard/easy argument shows that the Boolean Hierarchy cannot collapse unless the Polynomial Hierarchy also collapses. The results shown in this regard are improvements over those previously shown by Kadin. Furthermore, it is shown that the hard/easy argument can be adapted for Boolean hierarchies over incomplete NP languages. That is, under the assumption that certain incomplete languages exist, the Boolean hierarchies over those languages must be proper (infinite) hierarchies. Finally, this thesis gives an application of the hard/easy argument to resolve the complexity of a natural problem - the unique satisfiability problem. This last refinement of the hard/easy argument also points out some long-ignored issues in the definition of randomized reductions.

title: Real Functions for Representation of Rigid Solids
abstract: A range of values of a real function f : $E^{d} $\rightarrow \Re$ can be used to implicitly define a subset of Euclidean space E^{d}. Such `implicit functions' have many uses in geometric and solid modeling. This paper focuses on the properties and construction of real functions for the representation of rigid solids (compact, semi-analytic, and regular subsets of E^{d}). We review some known facts about real functions defining compact semi-analytic sets, and their applications. The theory of R-functionsdeveloped in [Rva82] provides means for constructing real function representations of solids described by the standard (non-regularized) set operations. But solids are not closed under the standard set operations and such representations are rarely available in modern modeling systems. More generally, assuring that a real function f represents a regular set may be difficult. Until now, the regularity has either been assumed, or treated in an ad hoc fashion. We show that topological and extremal properties of real functions can be used to test for regularity, and discuss procedures for constructing real functions with desired properties for arbitrary solids.

title: SimLab: Automatically Creating Physical Systems Simulators
abstract: SimLab, a software environment for creating simulators directly from computer-readable physics models, is based on the following concept: creating physical systems simulators should be as simple as describing the underlying physics to a colleague. Rather than programming in a conventional programming language, a SimLab user expresses physics models (and thus simulators) directly in terms of the concepts, quantities, and equations familiar to a scientist or engineer. The benefits of the SimLab approach include: 1) reducing the time and effort required to create simulators, 2) providing more understandable and reliable simulators, and 3) support for more sophisticated simulators, e.g., for multiple domain problems, which have proved intractible in the past.

title: Sensor Interpretation and Task-Directed Planning Using Perceptual Equivalence Classes
abstract: We consider how a robot may interpret its sensors and direct its actions so as to gain more information about the world, and to accomplish manipulation tasks. The key difficulty is uncertainty, in the form of noise in sensors, error in control, and unmodelled or unknown aspects of the environment. Our research focuses on general techniques for coping with uncertainty, specifically, to sense ther state of the task, adapt to changes, and reason to select actions to gain information and achieve the goal. Sensors yield partial information about the world. When we interrogate the environment through our sensors, we in effect view a projection of the world onto the space of possible sensor values. We investigate the structure of this sensor space and its relationship to the world. We observe that sensors partition the world into perceptual equivalence classes, that can serve as natural "landmarks." By analyzing the properties of these equivalence classes we develop a "lattice" and a "bundle" structure for the information available to the robot through sensing and action. This yields a framework in which we develop and characterize algorithms for sensor-based planning and reasoning.

title: Tools and Techniques for Adding Fault Tolerance to Distributed and Parallel Programs
abstract: The scale of parallel computing systems is rapidly approaching dimensions where fault tolerance can no longer be ignored. No matter how reliable the individual components may be, the complexity of these systems results in a significant probability of failure during lengthy computations. In the case of distributed memory multiprocessors, fault tolerance techniques developed for distributed operating systems and applications can be applied also to parallel computations. In this paper we survey some of the principal paradigms for fault-tolerant distributed computing and discuss their relevance to parallel processing. One particular technique - passive replication - is explored in detail as it forms the basis for fault tolerance in the Paralex parallel programming environment. Keywords: Parallel processing, reliability, transactions, checkpointing, recovery, replication, reliable broadcast, causal ordering, Paralex.

title: Paralex: An Environment for Parellel Programming in Distributed Systems
abstract: Modern distributed systems consisting of powerful workstations and high-speed interconnection networks are an economical alternative to special-purpose super computers. The technical issues that need

to be addressed in exploiting the parallelism inherent in a distributed system include heterogeneity, high-latency communication, fault tolerance and dynamic load balancing. Current software systems for parallel programming provide little or no automatic support towards these issues and require users to be experts in fault-tolerant distributed computing. The Paralex system is aimed at exploring the extent to which the parallel application programmer can be liberated from the complexities of distributed systems. Paralex is a complete programming environment and makes extensive use of graphics to define, edit, execute and debug parallel scientific applications. All of the necessary code for distributing the computation across a network and replicating it to achieve fault tolerance and dynamic load balancing is automatically generated by the system. In this paper we give an overview of Paralex and present our experiences with a prototype implementation

title: Run-time Support for Dynamic Load Balancing and Debugging in Paralex
abstract: Paralex is a programming environment for developing and executing parallel applications in distributed systems. The user is spared complexities of distributed programming including remote execution, data representation, communication, synchronization and fault tolerance as they are handled automatically by the system. Once an application starts execution in a distributed system, it may be interacted with at two levels: by Paralex itself to achieve automatic fault tolerance and dynamic load balancing; or by the user in association with performance tuning and debugging. In this paper, we describe the set of monitors and control mechanisms that constitute the Paralex run-time system and their use for implementing dynamic load balancing and debugging.

title: Fault-Tolerant Management of Distributed Applications Using the Reactive System Architecture
abstract: Distributed applications are becoming increasingly pervasive, and difficult to manage. Examples of distributed applications include operating system servers and clients on a network, programs performing distributed computations, and systems constructed by integrating stand-alone programs. This thesis argues that distributed applications can be managed efficiently by using a reactive system architecture. A reactive system consists of a control component continuously responding to changes in an environment component. This structure is applied to distributed application management by casting the programs making up the application as the environment and super-imposing a layer of control. By acting upon conditions sensed in the environment, the control layer can respond to changes in the distributed application, ensuring that it functions in a well-behaved manner. This thesis also presents the Meta toolkit, which provides primitives for controlling distributed applications using the reactive system architecture. The application components are instrumented with sensors and actuators - routines that respectively read and modify the application state. Control of the application is carried out via guarded commands, which are distributed for execution by either stubs coresident with programs in the application or by special servers. Distributing the control program results in greater responsiveness and efficiency but requires certain consistency problems to be addressed. Furthermore, the Meta toolkit supports fault-tolerant execution of guarded commands through the use of replicated servers. This toolkit has been implemented and is completely functional, and this thesis contains extensive performance figures for the toolkit.

title: Constructive Recognizability for Task-Directed Robot Programming
abstract: The primary goal of our research is task-level planning. We approach this goal by utilizing a blend of theory, implementation, and experimentation. We investigate task-level planning for autonomous agents, such as mobile robots, that function in an uncertain environment. These robots typically have very approximate, inaccurate, or minimal models of the environment. For example, although the geometry of its environment is crucial to determining its performance, [footnote:I.e., what the geometry is will have a key role in determining the robot's actions or behavior.] a mobile robot might only have a partial, or local "map" of the world. Similarly, the expected effects of a robot's actuators critically influence its selection of actions to accomplish a goal, but a robot may have only a very approximate, or local predictive ability with regard to forward-simulation of a control strategy. While mobile robots are typically equipped with sensors in order to gain information about the world, and to compensate for errors in actuation and prediction, these sensors are noisy, and in turn provide inaccurate information. We investigate an approach whereby the robot attempts to acquire the necessary information about the world by planning a series of experiments [footnote: The robot (not the researchers!) performs the experiments, to gain information about the world.] using the robot's sensors and actuators, and building data-structures based on the robot's observations of these experiments. A key feature of this approach is that the experiments the robot performs should be driven by the information demands of the task. That is, in performing some task, the robot may enter a state in which making progress towards a goal requires more information about the world (or its own state). In this case, the robot should plan experiments which can disambiguate the situation. When this process is driven by the information demands of the task, we believe it is an important algorithmic technique to effect task-directed sensing. This introductory survey article discusses: 1. A theory of sensor interpretation and task-directed planning using perceptual equivalence classes, intended to be applicable in highly uncertain or unmodelled environments, such as for a mobile robot. 2. Algorithmic techniques for modelling geometric constraints on recognizability, and the building of internal representations (such as maps) using these constraints. 3. Explicit encoding of the information requirements of a task using a lattice (information hierarchy) of recognizable sets, which allows the robot to perform experiments to recognize a situation or a landmark. 4. The synthesis of robust mobot programs using the geometric constraints, constructive recognizability experiments, and uncertainty models imposed by the task. We discuss how to extend our theory and the geometric theory of planning to overcome challenges of the autonomous mobile robot domain. One of our most important goals is to show how our theory can be made constructive and algorithmic. We propose a framework for mobot programming based on constructive recognizability, and discuss why it should be robust in uncertain environments. Our objective is to demonstrate the following: When recognizability is thusly constructive, we naturally obtain task-directed sensing strategies, driven by the information demands encoded in the structure of the recognizable sets. A principled theory of sensing and action is crucial in developing task-level programming for autonomous mobile robots. We propose a framework for such a theory, providing both a precise vocabulary and also appropriate computational machinery for working with issues of information flow in and through a robot system equipped with various types of sensors and operating in a dynamic, unstructured environment. We are implementing the theory and testing it on mobile robots in our laboratory.

title: Task-Level Planning and Task-Directed Sensing for Robots in Uncertain Environments
abstract: The primary goal of our research is task-level planning. We approach this goal by utilizing a blend of theory, implementation, and experimentation. We propose to investigate task-level planning for autonomous agents, such as mobile robots, that function in an uncertain environment. These robots typically have very approximate, inaccurate, or minimal models of the environment. For example, although the geometry of its environment is crucial to determining its performance, a mobile robot might only have a partial, or local "map" of the world. Similarly, the expected effects of a robot's actuators critically influence its selection of actions to accomplish a goal, but a robot may have only a very approximate, or local predictive ability with regard to forward-simulation of a control strategy. While mobile robots are typically equipped with sensors in order to gain information about the world, and to compensate for errors in actuation and prediction, these sensors are noisy, and in turn provide inaccurate information. We propose to investigate an approach whereby the robot attempts to acquire the necessary information about the world by planning a series of experiments using the robot's sensors and actuators, and building data-structures based on the robot's observations of these experiments. A key feature of this approach is that the experiments the robot performs should be driven by the information demands of the task. That is, in performing some task, the robot may enter a state in which making progress towards a goal requires more information about the world (or its own state). In this case, the robot should plan experiments which can disambiguate the situation. When this process is driven by the information demands of the task, we believe it is an important algorithmic technique to effect task-directed sensing. Plan projects focus on: 1. A theory of sensor interpretation and task-directed planning using perceptual equivalence classes, intended to be applicable in highly uncertain or unmodelled environments, such as for a mobile robot. 2. Algorithmic techniques for modelling geometric constraints on recognizability, and the building of internal representations (such as maps) using these constraints. 3. Explicit encoding of the information requirements of a task using a lattice (information hierarchy) of recognizable sets, which allows the robot to perform experiments to recognize a situation or a landmark. 4. The synthesis of robust mobot programs using the geometric constraints, constructive recognizability experiments, and uncertainty models imposed by the task. We propose to (a) continue our research and develop the theory fully, (b) use tools and concepts from the geometric theory of planning where appropriate, and (c) extend our theory and the geometric theory of planning where necessary to overcome challenges of the autonomous mobile robot domain. One of our most important goals is to show how our theory can be made constructive and algorithmic. We propose a framework for mobot programming based on constructive recognizability, and discuss why it should be robust in uncertain environments. Our objective is to demonstrate the following: When recognizability is thusly constructive, we naturally obtain task-directed sensing strategies, driven by the information demands encoded in the structure of the recognizable sets. A principled theory of sensing and action is crucial in developing task-level programming for autonomous mobile robots. We propose a framework for such a theory, providing both a precise vocabulary and also appropriate computational machinery for working with issues of information flow in and through a robot system equipped with various types of sensors and operating in a dynamic, unstructured environment. We will implement the theory and test it on mobile robots in our laboratory.

title: The Data Structure Accelerator Architecture
abstract: We present a fine grained, massively parallel SIMD architecture called the data structure accelerator and demonstrate its use in a number of problems in computational geometry. This architecture is extremely dense and highly scalable. Systems of 10^6 processing elements can be feasibly embedded in work stations. We advocate that this architecture be used in tandem with conventional single sequence machines and with small scale, shared memory multiprocessors. We present a language for programming such heterogeneous systems that smoothly encorporates the SIMD instructions of the data structure accelerator with conventional single sequence code. title: Design Alternatives for Process Group Membership and Multicast
abstract: Process groups are a natural tool for distributed programming, and are increasingly important in distributed computing environments. However, there is little agreement on the most appropriate semantics for process group membership and group communication. These issues are of special importance in the Isis system, a toolkit for distributed programming [Bir91]. Isis supports several styles of process group, and a collection of group communication protocols spanning a range of atomicity and ordering properties. This flexibility makes Isis adaptable to a variety of applications, but is also a source of complexity that limits performance. This paper reports on a new architecture that arose from an effort to simplify Isis process group semantics. Our findings include a refined notion of how the clients of a group should be treated, what the properties of a multicast primitive should be when systems contain large numbers of overlapping groups, and a new construct called the causality domain. As an illustration, we apply the architecture to the problem of converting processes into fault-tolerant process groups in a manner that is "transparent" to other processes in the system. A system based on this architecture is now being implemented in collaboration with the Chorus and Mach projects. Keywords: distributed computing, fault-tolerance, Isis, process groups, virtual synchrony, causal multicast, atomic broadcast.

title: Saving Queries With Randomness
abstract: In this paper, we provide tight bounds on the success probabilities of randomized reductions between various classes in the Boolean and Bounded Query Hierarchies. The P$^{SAT\Vert[k]}$ $\leq^{P}_{m}$ - complete language randomly reduces to a language in P$^{SAT\Vert[k-1]}$ with a one-sided error probability of 1/$\lceil$k/2$\rceil$. If two-sided error is allowed, then we show that a much lower error probability of 1/(k + 1) can be achieved. We prove that both these reductions are almost optimal by showing that the error probabilities cannot be reduced by even 1/poly, unless the PH collapses. These tight bounds precisely characterize the power and limitations of randomness in saving a query to SAT. These results can be used to identify optimal probability thresholds which determine when languages complete under randomized reductions inherit the hardness properties associated with $\leq^{P}_{m}$ - complete languages. Using these thresholds we prove hardness properties for some languages in these classes which are not $\leq^{P}_{m}$ - complete in certain relativized worlds. We also explore the relationship between randomization and functions computable using bounded queries to SAT. For any function $h (n) = O(log n), we show that there is a function f computable using $h(n)$ nonadaptive queries to SAT, which cannot be computed correctly with probability 1/2+1/poly by any randomized machine which makes less than $h(n)$ adaptive queries to any oracle, unless PH collapses.

title: A Formal Definition of Unnecessary Computation In Functional Programs
abstract: Our goal is to develop a new and highly flexible approach to program optimization. Instead of applying rote, high-level transformations, we seek to derive optimizations automatically from broad and intuitive principles. Toward that end this paper presents a new formalism for first-order, purely functional programs, then uses the formalism to give a rigorous statement of a principle of optimization. The formalism occupies three levels. At the lowest level is the trace graph, a finite, graph-like structure that describes a single terminating path of execution through a functional program. At the middle level is the trace graph set, which describes a set of paths of execution; a certain kind of trace graph set, the executable set, describes the full set of paths for a single deterministic program. At the highest level is the trace grammar, a graph grammar that generates a trace graph set. While trace graph sets may be infinite, trace grammars are finite objects with a natural, subroutine-like recursive structure. We use the formalism to give a rigorous statement of a well-known principle of optimization, namely, that programs should not make any unnecessary computations. This principle is so obvious that it is often overlooked, but it underlies many common compiler optimizations and other, more exotic program transformations. Our formal statement of the principle unifies and illuminates many optimizing transformations. Our work in progress is the construction of an optimizer that derives optimizations directly from our formal principle. This paper concludes with an overview of this optimizer and some preliminary experimental results.

title: On Isomorphisms and Density of NP and Other Complete Sets
abstract: If all NP complete sets are isomorphic under deterministic polynomial time mappings (p-isomorphic) then P $\neq$ NP and if all PTAPE complete sets are p-isomorphic then P $\neq$ PTAPE. We show that all NP complete sets known (in the literature) are indeed p-isomorphic and so are the known PTAPE complete

sets. Thus showing that, in spite of the radically different origins and attempted simplification of these sets, all the known NP complete sets are identical but for polynomially time bounded permutations. Furthermore, if all NP complete sets are p-isomorphic then they must have similar densities and, for example, no language over a single letter alphabet can be NP complete, nor can any sparse language over an arbitrary alphabet be NP complete. We show that complete sets in EXPTIME and EXPTAPE cannot be sparse and therefore they cannot be over a single letter alphabet. Similarly, we show that the hardest context-sensitive languages cannot be sparse. We also relate the existence of sparse complete sets to the existence of simple combinatorial circuits for the corresponding truncated recognition problem of these languages.

title: Logics and Models of Real Time: A Survey
abstract: We survey logic-based and automata-based languages and techniques for the specification and verification of real-time systems. In particular, we discuss three syntactic extensions of temporal logic: time-bounded operators, freeze quantification, and time variables. We also discuss the extension of finite-state machines with clocks and the extension of transition systems with time bounds on the transitions. All of the resulting notations can be interpreted over a variety of different models of time and computation, including linear and branching time, interleaving and true concurrency, discrete and continuous time. For each choice of syntax and semantics, we summarize the results that are known about expressive power, algorithmic finite-state verification, and deductive verification.

title: Timed Transition Systems
abstract: We incorporate time into an interleaving model of concurrency. In timed transition systems, the qualitative fairness requirements of traditional transition system are replaced (and superseded) by quantitative lower-bound and upper-bound timing constraints on transitions. The purpose of this paper is to explore the scope of applicability for the abstract model of timed transition systems. We demonstrate that the model can represent a wide variety of phenomena that routinely occur in conjunction with the timed execution of concurrent processes. Our treatment covers both processes that are executed in parallel on separate processors and communicate either through shared variables or by message passing, and processes that time-share a limited number of processors under a given scheduling policy. Often it is this scheduling policy that determines if a system meets its real-time requirements. Thus we explicitly address such questions as time-outs, interrupts, static and dynamic priorities.

title: Performance in Flexible Distributed File Systems
abstract: There are many existing distributed file systems. Each file system provides a different degree of performance and safety. In this context, performance is the time required to satisfy individual requests, and safety is the set of guarantees that the file system provides to users. In this thesis, we characterize many of the trade-offs between performance and safety. We include numerical relationships whenever possible. As a corollary, it is shown that a flexible file system - one that provides a wide range of possible safety properties - can also have very good performance. This thesis uses two main approaches, practical and theoretical. The practical approach centers around the Deceit File System. Deceit supports file replication, file migration and a sophisticated update control protocol. Deceit can behave like a plain Sun Network File System (NFS) server and can be used by any NFS client without modifying any client software. Deceit servers are interchangeable and collectively provide the illusion of a single large server machine to its clients. The theoretical approach presents several results that are applicable to all distributed file systems. A careful analysis of many systems yielded insights into the behavior of successful file systems. We formalize the relationships between safety conditions exposed by this analysis. We also determine the cost of reading and writing a file given different sets of safety conditions. In conclusion, we find that Deceit does not totally meet the goal of being efficient under all possible sets of requirements. Deceit is highly efficient for cases that require a high degree of replication and safety, but it is inefficient in cases where very specific optimizations are possible. However, the flexibility that Deceit provides is still very useful. For example, we show that writing to a file with three replicas costs a factor of 5 more messages more than writing to a file with one replica. Allowing asynchronous disk writes instead of synchronous writes can decrease latency by a factor of more than 30. Since Deceit allows the user to choose among these possibilities, dramatic performance gains can be achieved in many cases.

title: Quality Mesh Generation in Three Dimensions
abstract: We show how to triangulate a three dimensional polyhedral region with holes. Our triangulation is optimal in the following two senses: First, our triangulation achieves the best possible aspect ratio up to a constant. Second, for any other triangulation of the same region into m triangles with bounded aspect ratio, our triangulation has size n = O(m). Such a triangulation is desired as an initial mesh for a finite element mesh refinement algorithm. Previous three dimensional triangulation schemes either worked only on a restricted class of input, or did not guarantee well-shaped tetrahedra, or were not able to bound the output size. We build on some of the ideas presented in previous work by Bern, Eppstein and Gilbert,

who have shown how to triangulate a two dimensional polyhedral region with holes, with similar quality and optimality bounds.

title: On The Local Convergence of The Byrd-Schnabel Algorithm For Constrained Optimization
abstract: Most reduced Hessian methods for equality constrained problems use a basis for the null space of the matrix of constraint gradients and posess superlinearly convergent rates under the assumption of continuity of the basis. However, computing a continuously varying null space basis is not straightforward. Byrd and Schnabel [2] propose an alternative implementation that is independent of the choice of null space basis, thus obviating the need for a continuously varying null space basis. In this note we prove that the primary sequence of iterates generated by one version of their algorithm exhibits a local 2-step Q-superlinear convergence rate. We also establish that a sequence of "midpoints", in a closely related algorithm, is (1-step) Q-superlinearly convergent. Key words: constrained optimization, null space, superlinear convergence, reduced Hessian.

title: Shape and Motion from Image Streams: a Factorization Method: Full Report on the Orthographic Case
abstract: Inferring scene geometry and camera motion from a stream of images is possible in principle, but is an ill-conditioned problem when the objects are distant with respect to their size. We have developed a factorization method that can overcome this difficulty by recovering shape and motion without computing depth as an intermediate step. An image stream can be represented by the 2F x P measurement matrix of the image coordinates of P points tracked through F frames. We show that under orthographic projection this matrix is of rank 3. Using this observation, the factorization method uses the singular value decomposition technique to factor the measurement matrix into two matrices which represent object shape and camera motion, respectively. The method can also handle and obtain a full solution from a partially filled-in measurement matrix, which occurs when features appear and disappear in the image sequence due to occlusions or tracking failures. The method gives accurate results, and does not introduce smoothing in either shape or motion. We demonstrate this with a series of experiments on laboratory and outdoor image

streams, with and without occlusions.

title: Fault-Tolerant Broadcasts and Multicasts: The Problem of Inconsistency and Contamination
abstract: An increasingly important paradigm for designing fault-tolerant applications for distributed systems is based on processes that communicate exclusively via fault-tolerant broadcasts and multicasts. Most broadcasts that are described in the literature, such as reliable broadcast, causal broadcast, atomic broadcast and the corresponding multicasts, specify the behavior of correct processes, but do not impose requirements on the behavior of faulty processes. Such specifications allow a process that fails during a broadcast to reach an "inconsistent" state (e.g., by omitting the delivery of a message), and to continue execution from that state. This faulty process may later broadcast messages that "contaminate" the correct processes. In this thesis, we argue that such inconsistency and contamination can complicate the design of applications, and we present fault-tolerant broadcast and multicast protocols that prevent inconsistency and contamination. We begin by formally defining a hierarchy of different types of process inconsistency; these definitions are general, and hence are valid for any broadcast specification. Intuitively, contamination is the "spread" of inconsistency from faulty processes to correct processes. We formalize this concept and show that only two forms of contamination arise from our hierarchy of types of inconsistency. Atomic broadcast and atomic multicast are powerful communication abstractions that are central to many systems (e.g., Isis, and IBM's HAS), and to Lamport's state machine approach to fault-tolerance. Using our general definitions of inconsistency and contamination, we derive necessary and sufficient conditions to prevent inconsistency and/or contamination when processes communicate using atomic broadcast. We also derive similar conditions for atomic multicast. Based on these conditions, we develop atomic broadcast protocols that prevent inconsistency and/or contamination. In general, the prevention of inconsistency is a stronger requirement (and more difficult and more expensive to enforce) than the prevention of contamination. We characterize a class of problems for which the prevention of contamination is as good as the prevention of inconsistency. We show that an application that solves a problem in this class under the simplifying assumption that both inconsistency and contamination are prevented remains correct even if it uses a (less expensive) broadcast protocol that only prevents contamination.

title: From the Buffon Needle Problem to the Kreiss Matrix Theorem
abstract: In this paper we present a theorem concerning the arc length on the Riemann sphere of the image

of the unit circle under a rational function. But our larger purpose is to tell a story. We thought at first that the story began in 1962 with the Kreiss matrix theorem, the application that originally motivated us. However, our arc length question turns out to be more interesting than that. The story goes back to the famous "Buffon needle problem" of 1777.

title: PL/CT - A Terminal Version of PL/C - Release 2
abstract: PL/CT is a special version of PL/C designed to permit programs to be run interactively from a typewriter terminal. It is completely compatible with normal PL/C - that is, the source languages accepted by PL/C and PL/CT are identical and the results of execution are exactly the same. Hence, a program can be developed and tested under PL/CT and subsequently run under normal PL/C (or vice versa). PL/CT permits the user to interact with the program during its execution. Output will be printed on the terminal and input data may be requested from the terminal. The course and rate of execution can be controlled from the terminal. It is also possible to interrupt execution and display and alter the values of variables. However, the source program itself cannot be changed under PL/CT. PL/CT receives a complete program, compiles it, and then executes it in interactive mode. But to make any change in the program it is necessary to leave PL/CT, make the change under the CMS editor, and then present the modified program to PL/CT for complete recompilation. This Guide provides only minimal information about CMS, perhaps sufficient for very straightforward programming tasks.

title: Dynamic Simulation of Non-Penetrating Rigid Bodies
abstract: This thesis examines the problems and difficulties in the forward dynamic simulation of rigid bodies subject to non-penetration constraints. By adopting a simple but well-defined model of rigid body dynamics, we are able to focus on and gain insight into some of the inherent difficulties of rigid body simulation. Additionally, computationally practical solutions to some of the problems encountered in this thesis are presented. Enforcing non-penetration constraints is essentially a two step process. The first step of the simulation involves the detection of potential contacts between bodies. This thesis presents collision detection algorithms for the dynamic simulation of bodies that are composed of both polyhedra and convex closed curved surfaces. The collision detection algorithms exploit temporal coherence to achieve fast running times and are a practical solution to the problem of collision detection during simulation. The second step of the simulation involves the computation of the contact forces between bodies that maintain the non-penetration constraint. This thesis considers first the problem of computing contact forces between a pair of bodies that contact at a point without friction. A mathematical formulation for the contact force between the bodies is presented, and then modified to yield a formulation that is computationally practical for use in a simulator. After considering the dynamics of single point contacts, systems with multiple contacts are considered both in terms of computational complexity measures and practical solution methods. The methods used in this thesis to compute constraint forces are also theoretically and practically compared with a popular method for preventing inter-penetration called the "penalty method". After considering frictionless systems, this thesis considers systems of bodies that behave according to the classical Coulomb model of friction (which includes both sliding and dry friction). This leads us to consider systems in which there are no solutions to the classical constraint force equations, as well as systems which admit multiple solutions for the constraint

force equations and whose subsequent behavior is thus indeterminate. Both computational and practical complexity results for simulating such systems are discussed.

title: Using Consistent Subcuts for Detecting Stable Properties
abstract: We present a general protocol for detecting whether a property holds in a distributed system, where the property is a member of a subclass of stable properties we call the locally stable properties. Our protocol is based on a decentralized method for constructing a maximal subset of the local states that are mutually consistent, which in turn is based on a weakened version of vector time stamps. The structure of our protocol lends itself to refinement, and we demonstrate its utility by deriving some specialized property-detection protocols, including two previously-known protocols that are known to be efficient.

title: Access Normalization: Loop Restructuring for NUMA Compilers
abstract: A common feature of many scalable parallel machines is non-uniform memory access - a processor can access data in its local memory ten to a thousand times faster than it can access non-local data. In addition, when a number of remote accesses must be made, it is usually more efficient to use block transfers of data rather than to use many small messages. To run well on such machines, software must exploit these features. We believe it is too onerous for a programmer to do this by hand, so we have been exploring the use of restructuring compiler technology for this purpose. In this paper, we start with a language like FORTRAN-D with user-specified data distributions and develop a systematic loop transformation strategy called access normalization that restructures loop nests to exploit both locality and block transfers wherever possible. We demonstrate the power of our techniques using routines from the BLAS (Basic Linear Algebra Subprograms) library. Our loop transformation strategy is expressed in the framework of invertible matrices and integer lattice theory and it is an important generalization of Banerjee's framework of unimodular matrices.

title: Provably-Good Approximation Algorithms for Optimal Kinodynamic Robot Motion Plans
abstract: The kinodynamic planning problem is to synthesize a robot motion obeying simultaneous kinematic and dynamics constraints. To maximize robot performance we can consider optimal kinodynamic planning: for a given robot system, find a minimal-time trajectory that goes from a start state to a goal state, avoids

obstacles by a speed-dependent safety margin, and respects the dynamics laws and dynamics bounds governing the system. In general, previous work on algorithmic motion planning does not address dynamics; furthermore, even in simple cases, finding exact globally-optimal solutions is $\cal NP$-hard. In response, we obtain provably-good, polynomial-time approximation algorithms that synthesize optimal kinodynamic trajectories. These algorithms forge new mathematical links between control theory and complexity theory, and our analysis investigates how discrete-control trajectories can approximate optimal solutions We cast optimal kinodynamic planning into the form of an ϵ-approximation problem in which $\epsilon greater than 0$ characterizes closeness to optimality in terms of trajectory time, observance of the safety margin and closeness to the start and goal states If T_{opt} is the time of an optimal trajectory, then an ϵ-optimal trajectory takes at most (1 + ϵ)T_{opt} time. We present (pseudo)-polynomial-time ϵ-approximation algorithms for a family of robot classes, including fully-controllable open kinematic chains. These algorithms run in time polynomial in $\frac{1}{\epsilon}$ and the geometric complexity of the constraints. The basic idea behind the algorithms is to reduce the trajectory planning problem to a shortest-path problem on a polynomial-sized reachability graph embedded in the robot state space. These graphs are generated by control primitives and a timestep that the algorithm chooses to ensure ϵ- optimality. To obtain our complexity and approximation results, we introduce both continuous and combinatorial tools to analyze the robot's dynamical system. These include scaling-tracking proof methods that capture the key insight necessary for provably-good results, tracking lemmas on how closely we can approximate an optimal or time-rescaled optimal trajectory, constructive trajectory proofs, adversary game proofs and Time-Safety planning trade-offs. We also decribe an implementation and experiments in a restricted domain.

title: Stable Numerical Algorithms for Equilibrium Systems
abstract: An equilibrium system (also known as a KKT system, a saddlepoint system or a sparse tableau) is a square linear system with a certain structure. G. Strang has observed that equilibrium systems arise in optimization, finite elements, structural analysis and electrical networks. Recently, G. W. Stewart established a norm bound for a type of equilibrium system in the case that the "stiffness" portion of the system is very ill-conditioned. In this paper, we investigate the algorithmic implications of Stewart's result. We show that all standard textbook algorithms for equilibrium systems are unstable. Then we show that a certain hybrid method has the right stability property.

title: On Parsing Context Free Languages in Parallel Environments
abstract: Non-canonical generalization of several bottom-up parsing methods, including Simple Precedence, LR(k), SLR(k), and LALR(k) are considered. It is seen that these methods can readily be made to generate many concurrent reductions and thus can be used to advantage in parallel environments. it is suggested that such methods could be used to produce practical parsers for such parallel computers as the CDC Star-100. Further, the grammar classes defined by these parallel methods are studied and compared with the grammar classes defined by a number of serial parsing techniques.

title: Area-Universal Interconnection Networks for VLSI Parallel Computers
abstract: A central issue in the design of a general-purpose parallel computer is the choice of an interconnection network and an associated algorithm for routing messages through it. The main results of this thesis are two new interconnection networks, the pruned butterfly and the sorting fat-tree and deterministic routing algorithms for them. Both networks are area-universal, i.e., they can simulate any other routing network fitting in similar VLSI chip area with only polylogarithmic slowdown. Previous area-universal networks were either for the off-line problem, where the message set to be routed is known in advance and substantial precomputation is permitted, or involved randomization, yielding results that hold only with high probability. The two networks introduced here are the first that are simultaneously deterministic and on-line and they use two substantially different routing techniques. The performance of the routing algorithms depends on the difficulty of the problem instance, which is measured by a quantity λ known as the load factor. The pruned butterfly algorithm runs in time O (λlog^2 N), where N is the number of possible sources and destinations for messages and λ is assumed to be polynomial in N. The sorting fat-tree algorithm runs in O ($\lambda log N + log^2 N$) time for a restricted class of message sets including partial permutations. Several related results are also presented in this thesis. A nontrivial lower bound on wire area is proven for a class of tree-based networks that do not modify the content of messages are shown to be subject to an area-time tradeoff. This lower bound implies the sorting fat-tree's area-time performance is optimal for a wide range of possible values for λ. Other results of this work include a new type of sorting circuit and an area-universal VLSI circuit.

title: On Branching Numbers of Normal Manifolds
abstract: Let $\cal M$ be a finite piecewise linear (pl) manifold of IR^n, and P : $IR^n \rightarrow IR^n$ be pl with respect to $\cal M$, i.e. P is affine on each set in $\cal M$. The branching number of $\cal M$, Kuhn and Lowen [8], is the maximum number of sets in $\cal M$ that can contain any common face of codimension 2. [8, Thm. 5.3] shows that if $\cal M$ has branching number less than or equal to 4, then P is a homeomorphism if and only if it is coherently oriented, i.e. the determinants of P on the sets in $\cal M$ have the same nonzero sign. Let C be a nonempty polyhedral convex set in IR^n, and $A \in IR^{nxn}$. Robinson [14] defines a finite pl manifold $\cal N_C$ of IR^n called the normal manifold of C; and the normal map A_C : $IR^n \rightarrow IR^n$ induced by (A, C), which is pl with respect to $\cal N_C$. [14, Thm. 4.3] shows that A_C is homeomorphic if and only if it is coherently oriented. We show that $\cal N_C$ has branching number less than or equal to 4, hence Robinson's result is actually a corollary of Kuhn and Lowen's. Key Words: Piecewise linear, piecewise affine, branching number, normal map, pl-normal, normal manifold, homeomorphism, coherently oriented.

title: The Inherent Cost of Achieving Causal Consistency
abstract: We consider the problem of distinguishing causally-consistent global states in asynchronous distributed systems. Such states are fundamental to asynchronous systems, because they correspond to

possible simultaneous global states; their detection arises in a variety of distributed applications, including global checkpointing, deadlock detection, termination detection and broadcasting. A consistent-cut protocol is a protocol which in every run will designate for each processor a state, in such a way that these states together form a consistent cut. We analyze the cost of achieving causal consistency in terms of the extent to which a consistent-cut protocol delays events of the underlying system, and the message-complexity required by any such protocol. We refer to the delaying action of a protocol as inhibition. We consider a spectrum of protocol capabilities based on the type of inhibition that occurs: we distinguish local versus global inhibition and prove fundamental relationships between these concepts and the ability to determine causally-consistent states. A protocol using local inhibition may cause the delay of some of a processor's events until that processor has performed some number of local actions; a protocol using global inhibition may force the delay of some of a processor's events until that procesor has received some communication from other processors. Based on a variety of system and protocol characteristics, including the ability to locally or globally inhibit particular types of events, we give several impossibility results and examine some existing protocols. We are then able to present a thirty-six-case summary of protocols and impossibility results for the determination of causally-consistent states as a function of those characteristics. In particular, we demonstrate that local inhibition is necessary and sufficient to solve this problem for general FIFO systems, while global send inhibition is necessary and sufficient for general non-FIFO systems. Regarding message complexity, we demonstrate that a globally inhibitory consistent-cut protocol requires $O (N)$ messages where N is the number of processors in the system. This is true whether the protocol is designed to work for FIFO or non-FIFO systems; the exact lower bounds, however, differ in the two cases. We also prove that a consistent-cut protocol which uses local inhibition only requires O (N^{2}) messages, or, more precisely, O ($\vert \cal C \vert$), where $\cal C$ is the channel set of the system. This latter result illustrates a trade-off between the message complexity of a consistent-cut protocol and the degree of inhibition which it requires.

title: Higher-Order Concurrency
abstract: Concurrent programming is a useful technique for structuring many important classes of applications such as interactive systems. This dissertation presents an approach to concurrent language design that provides a new form of linguistic support for constructing concurrent applications. This new approach treats synchronous operations as first-class values in a way that is analogous to the treatment of functions as first-class values in languages such as ML. The mechanism is set in the framework of the language Concurrent ML (CML), which is a concurrent extension of Standard ML. CML has a domain of first-class values, called events, that represent synchronous operations. Synchronous message passing operations are provided as the base-event values, and combinators are provided for constructing more complex events from other event values. This mechanism allows programmers to define new synchronization and communication abstractions that are first-class citizens, which gives programmers the flexibility to tailor their concurrency abstractions to their applications. The dissertation is organized into three technical parts. The first part describes the design and rationale of CML and shows how first-class synchronous operations can be used to implement many of the communication mechanisms found in other concurrent languages. The second part presents the formal operational semantics of first-class synchronous operations and proves that the polymorphic type system used by CML is sound. The third part addresses practical issues. It describes the use of CML in non-trivial applications, describes the implementation and performance of CML on a single-processor computer, and discusses issues related to the use and implementation of CML on a shared-memory multiprocessor.

title: Automatic Structuring and Retrieval of Large Text Files
abstract: In many operational environments, large text files must be processed covering a wide variety of different topic areas. Aids must then be provided to the user that permit collection browsing and make it possible to locate particular items on demand. The conventional text analysis methods based on preconstructed knowledge-bases and other vocabulary-control tools are difficult to apply when the subject coverage is unrestricted. An alternative approach, applicable to text collections in any subject area, is introduced which uses the document collections themselves as a basis for the text analysis, together with sophisticated text matching operations carried out at several levels of detail. Methods are described for relating semantically similar pieces of text, and for using the resulting hypertext structures for collection browsing and information retrieval.

title: Abstract Value Constructors: Symbolic Constants for Standard ML
abstract: Standard ML (SML) has been used to implement a wide variety of large systems, such as compilers, theorem provers, graphics libraries and even operating systems. While SML provides a convenient, high-level notation for programming large applications, it does have certain deficiencies. One such deficiency is the lack of a general mechanism for assigning symbolic names to constant values. In this paper, we present a simple extension of SML that corrects this deficiency in a way that fits naturally with the semantics of SML. Our proposal is a generalization of SML's datatype constructors: we introduce constants that generalize nullary datatype constructors (like nil), and

title: Pseudospectra of the Linear Navier-Stokes Evolution Operator and Instability of Plane Poiseuille and Couette Flows: (preliminary report)
abstract: This is a rough, interim report on some new results concerning the stability of plane Poiseuille and Couette fluid flows, following upon recent work by Henningson and Reddy, Butler and Farrell, Gustavsson and others. We emphasize that the conclusions proposed here have not yet been checked carefully and are subject to change. Our principal results are as follows: 1. Plots of the spectra of the "full" Navier-Stokes operator for Poiseuille and Couette flows, i.e., without restriction to a wave number pair (α, β) or to even or odd modes ($\S\S$4,5). 2. Analogous plots for the pseudospectra of this operator. Comparison of the pseudospectra with the spectra gives a new interpretation of why the physics of these linear flow problems is not controlled by the location of the most unstable eigenvalue ($\S\S$4,5). 3. Demonstration that these pseudospectra predict the Butler-Farrell "optimal" transient energy growth ratios to within a factor of about 2 ($\S$6). 4. Demonstration that about 90% of the Butler-Farrell growth can be achieved by a 3$\times$3 linear model obtained by projecting the Navier-Stokes problem onto the space spanned by three dominant eigenmodes, for Couette flow, or four in the case of Poiseuille flow ($\S$8). 5. Demonstration that although 1 Orr-Sommerfeld mode and 3 Squire modes suffice for the 4$\times$4 model in the Poiseuille case, in keeping with a recent result of Gustavsson, one can do equally well with 2 modes of each kind or with 3 Orr-Sommerfeld modes and 1 Squire mode ($\S$8). 6. Demonstration that the minimal operator perturbation required to destabilize a stable flow has norm of order R^-^{2}, where R is the Reynolds number, though the distance of the least stable eigenvalue from the real axis is $O (R^-$^{1}) ($\S$7). 7. Presentation of a 2$\times$2 model illustrating that if the linear problems described above are capable of transient energy growth of order M (e.g., $M\approx$1000 according to Butler and Farrell), a weak and intrinsically energy-conserving nonlinear term can "bootstrap" that growth to a higher order such as M^2. This supports the view that although nonlinear terms are of course essential to the subcritical instability of fluid flows, the detailed nature of the nonlinear interactions may sometimes be relatively unimportant ($\S$2). 8. Adaptation of this "bootstrapping" idea to the fluid flows considered earlier, particularly the 3$\times$3 approximation for Couette flow with R=1000.

title: On Invariants of Sets of Points or Line Segments Under Projection
abstract: We consider the problem of computing invariant functions of the image of a set of points or line segments in $\Re^3$ under projection. Such functions are in principle useful for machine vision systems, because they allow different images of a given geometric object to be described by an invariant `key'. We show that if a geometric object consists of an arbitrary set of points or line segments in $\Re^3$, and the object can undergo a general rotation, then there are no invariants of its image under projection. For certain constrained rotations, however, there are invariants (e.g., rotation about the viewing direction). Thus, we precisely delimit the conditions for the existence or nonexistence of invariants of arbitrary sets of points or line segments under projection.

title: A Singular Loop Transformation Framework Based on Non-Singular Matrices
abstract: In this paper, we discuss a loop transformation framework that is based on integer non-singular matrices. The transformations included in this framework are called Λ-transformations and include permutation, skewing and reversal, as well as a transformation called loop scaling. This framework is more general than the existing ones; however, it is also more difficult to generate code in our framework. This paper shows how integer lattice theory can be used to generate efficient code. An added advantage of our framework over existing ones is that there is a simple completion algorithm which, given a partial transformation matrix, produces a full transformation matrix that satisfies all dependences. This completion procedure has applications in parallelization and in the generation of code for NUMA machines.

title: Periodic Updates in Processor Networks
abstract: In implementing parallel scientific applications, the crux is often efficiency in communication. So, it becomes important to abstract out and study frequently occurring patterns of communication. We describe one such abstraction, periodic update, which arises in such diverse areas as computational molecular dynamics, distributed systems and n-body simulations. Consider a synchronous network of processors. Every processor needs to know the status of every other processor. The status keeps changing and it is more important to know the correct status of nearer processors. The work done in maintenance of status information should be as little as possible. The periodic update problem is that of sending (and receiving) periodic status updates from every processor to every other processor in the network in order to maintain status information. The time interval between successive updates from one processor to another is given by some increasing function (the periodicity function) of the distance between them. Given a network and a periodicity function, we wish to find efficient protocols for the periodic update problem which have minimum delay (time elapsed between the sending of an update and its receipt) and minimum

peak bandwidth (maximum number of updates sent across any edge in one time-step). We present a general design paradigm and construct periodic update protocols for the one and two dimensional mesh networks for both polynomial and exponential periodicity functions. Given a periodicity function, we demonstrate a trade-off between delay and peak bandwidth. Then, using two general techniques, we transform minimum delay protocols into families of highly efficient protocols with performances spanning the entire spectrum from minimum delay to minimum peak bandwidth.

title: The Motion of Planar Compliantly-Connected Rigid Bodies in ContactWith Applications to Automatic Fastening
abstract: We consider the problem of planning and predicting the motion of a flexible object amidst obstacles in the plane. We model the flexible object as a rigid "root" body, attached to compliant members by torsional springs. The root's position may be controlled, but the compliant members move in response to forces from contact with the environment. Such a model encompasses several important and complicated mechanisms in mechanical design and automated assembly: snap-fasteners, latches, ratchet and pawl mechanisms, and escapements. The problem is to predict the motion of such a mechanism amidst fixed obstacles. For example, our algorithm could be used to determine whether a snap-fastener design can be assembled with a certain plan. In this paper, we analyze the physics of these flexible devices, and develop combinatorially precise algorithms for predicting their movement under a motion plan. Our algorithms determine when and where the motion will terminate, and also computes the time-history of contacts and mating forces. In addition to providing the first known exact algorithm that addresses flexibility in motion planning, we also note that our approach to compliance permits an exact algorithm for predicting motions under rotational compliance, which was not possible in earlier work. We discuss the following issues: the relevance of our approach to engineering (which we illustrate through the examples we ran using our system), the computational methods employed, the algebraic techniques for predicting motions in contact with rotational compliance, and issues of robustness and stability of our geometric and algebraic algorithms. Our computational viewpoint lies in the interface between differential theories of mechanics, and combinatorial collision detection algorithms. From this viewpoint, subtle mathematical difficulties arise in predicting motions under rotational compliance, such as the forced non-genericity of the intersection problems encountered in configuration space. We discuss these problems and their solutions. Finally, we extend our work to predict the forces on the manipulated objects as a function of time, and show how our algorithm can easily be extended to include uncertainty in control and initial conditions. With these extensions, we hope that our system could be used to analyze and design objects that are easy to assemble, even given control and sensing errors, and that require more force to disassemble than to mate.

title: Multicast Flow Control on Local Area Networks
abstract: The primary LAN technologies in use today --- ethernet, FDDI, and token-ring --- all provide hardware support for broadcast and multicast capability. However, distributed systems have traditionally used unicast messaging exclusively, even when multicast communication patterns arise. As the number of distributed applications grows, the load on networks caused by unnecessary unicasts will increase. In addition, for some applications performance and group size are limited by using unicast technologies for multicast. If multicast technologies are exploited, the network load caused by "redundant" packets will be reduced. Exploiting multicast will also improve the performance and scalability of some distributed applications. However, as distributed systems move towards exploiting multicast, multicast flow control protocols are becoming more important. Finding a general, effective solution for multicast flow control will help facilitate the exploitation of the multicast primitives provided in LANs and Wide Area Networks (WANs). This dissertation presents the results of an investigation into multicast performance on local area networks. An analysis of multicast flow control is presented which distinguishes between {\it rate reservation} and {\it rate control}, followed by a discussion of the major design issues associated with multicast flow control and a presentation of a proposed protocol family. The proposed protocol family is based on send-rate control. An unreliable and a reliable multicast flow control protocol based on the proposed family are presented. A study of the performance of these protocols is also presented. This dissertation concludes with an investigation into how well the proposed reliable multicast flow control protocol performs when used to disseminate messages. This dissertation argues that direct rate control has merit as a technique for multicast flow control on local area networks.

title: Efficient Geometric Algorithms for Robot Sensing and Control
abstract: This thesis addresses the problem of automatically generating solutions to robotics tasks that are specified at a high level. In particular, we consider the problems of robot motion planning and the planning of sensor placements. These problems are made difficult by a number of inherent factors. Foremost among these are uncertainty and geometric complexity. Uncertainty arises from the fact that the actions of robots are subject to error. Geometric complexity reflects the fact that real-world task environments are often complex. If we want robot strategies that are both practical and robust, we must develop algorithms that successfully deal with uncertainty and complex geometry. Much of the previous work in the area of task-level planning for robots fails to address at least one of these issues. Many theoretical approaches are algorithmically sophisticated, but do not handle uncertainty, and may be unimplementable in practice. On the other hand, real robot systems often employ simplistic strategies that do not take into account complex geometric interactions. This thesis seeks to bridge the gap between these two extremes. We present efficient planning algorithms for motion and sensing that are both practical and algorithmically sophisticated. Our motion planning algorithm computes one-step motion strategies that guarantee reaching a specified goal in the plane. To deal with uncertainty in robot control, we employ a control model that allows the robot to slide along obstacle surfaces, or comply with the environment. Our analysis of this algorithm yields a precise characterization of the complexity of one-step compliant motion planning with uncertainty. Sensors are needed within autonomous systems to provide execution-time feedback. In this thesis we develop a framework

for planning sensing strategies in a principled way. In particular, we present algorithms for computing the set of placements from which a sensor can monitor a region within a task environment. This work has many applications in the areas of assembly planning, cooperating robots, and robot surveillance. We have demonstrated the practicality of our approach by building a system of robot surveillance with mobile robots employing our strategies for sensor planning.

title: A Quasi-Newton L_{2}-Penalty Method for Minimization Subject toNonlinear Equality Constraints
abstract: We present a modified L_{2} penalty function method for equality constrained optimization problems. The pivotal feature of our algorithm is that at every iterate we invoke a special change of variables to improve the ability of the algorithm to follow the constraint level sets. This change of variables gives rise to a suitable block diagonal approximation to the Hessian which is then used to construct a quasi-Newton method. We show that the complete algorithm is globally convergent with a local Q-superlinearly convergence rate. Preliminary computational results are given for a few problems.

title: Verification Methods for the Divergent Runs of Clock Systems
abstract: We present a methodology for proving temporal properties of the divergent runs of reactive systems with real-valued clocks. A run diverges if time advances beyond any bound. Since the divergent runs of a system may satisfy liveness properties that are not satisfied by some convergent runs, the standard proof rules are incomplete if only divergent runs are considered. First, we develop a sound and complete proof calculus for divergence, which is based on translating clock systems into discrete systems. Then, we show that simpler proofs can be obtained for stronger divergence assumptions, such as unknown epsilon-divergence, which requires that all delays have a minimum duration of some unknown constant epsilon. We classify all real-time systems into an infinite hierarchy, according to how well they admit the translation of eventuality properties into equivalent safety properties.

title: Undecidability Results for Hybrid Systems
abstract: We illuminate the boundary between decidability and undecidability for hybrid systems. Adding any of the following decorations to a timed automaton makes the reachability problem undecidable: 1. a single stopwatch with weak (less than or equal to, greater than or equal to) edge guards 2. a single skewed clock with variable equality tests 3. a single two-slope clock with weak edge guards 4. a single memory cell with weak edge guards As a corollary, we obtain undecidability for linear hybrid systems with triangular differential inclusions, which have invariants of the form x' less than or equal to y'.

title: Automatic Hypertext Construction
abstract: The unprecedented growth of the World Wide Web illustrates the importance of hypertext as a method for organizing the rapidly expanding amount of on-line text. As document collections become larger and more dynamic, however, it is not feasible to construct more than an occasional hypertext manually. This thesis presents entirely automatic methods for gathering documents for a hypertext, linking them, and annotating those connections with a description of the type or nature of the link. The problem of automatically collecting related documents is addressed in Chapter 2, where robust Information Retrieval methods are applied to form high-quality links between documents. A local context check identifies links where ambiguous vocabulary erroneously suggests a relationship. Dynamic part retrieval is employed to select the portions of documents which are most related, allowing parts to be linked when it is more appropriate to link subtopics than entire documents. Chapter 3 presents a taxonomy of hypertext link types and defines the following three classes of links: "pattern-matching" links can be found using simple string-matching methods, "manual" links require substantial application of natural language understanding methods (which are currently beyond the state of the art), and "automatic" links are those which can be found using the methods of this thesis. Chapter 4 begins the work of automatic link typing by describing two novel graphical techniques for visualizing the relationship between two or more documents. "Uniform" visuals display the relationship between documents or document parts without regard to their relative sizes, whereas "varying" visuals include information about sizes and locations. Both methods highlight relationships between documents and motivate the automatic techniques of Chapter 5. Chapter 5, thus, demonstrates automatic methods for identifying the relationships depicted in the visualizations. Using an approach based upon graph simplification, this method automatically identifies revision, summary, expansion, equivalence, comparison, contrast, tangential, and aggregate links. Chapter 6 discusses an informal evaluation of the link typing. Though somewhat inconclusive, the evaluation demonstrates that automatic document linking performs well, but also indicates that much work remains to be done toward understanding automatic link typing.

title: Localization, Mapmaking, and Distributed Manipulation with Flexible,Robust Mobile Robots
abstract: Current mobile robots (mobots) have extremely limited usefulness in real-world applications, due primarily to low capability and low reliability. Current mobots cannot navigate in environments which have not been extensively engineered to be mobot-friendly; they are also incapable of performing useful duties at their destination. They often have poorly designed hardware and primitive software-development environments, making the development of new mobile robot protocols slow and difficult. In this thesis, we describe three ways to make mobile robots more usable. We present algorithms for mobile robot self-localization, a design paradigm for reliable mobile robots, and protocols for cooperative large-scale manipulation by mobile robots. Localization is the process of determining the robot's location within its environment. More precisely, it is a procedure which takes as input a geometric map, a current estimate of the robot's pose, and sensor readings, and produces as output an improved estimate of the robot's current pose (position and orientation). We describe an algorithm which performs mobile robot localization using a geometric model of the world and a point-and-shoot rang ing device. We also describe a rasterized version of this algorithm which we've implemented on a real mobile robot equipped with a laser rangefinder we designed. We next focus on the mobile robots themselves. We have designed and built several mobile robots at Cornell, that feature robustness, flexibility, and ease of programming. Using a modular design approach, we've attained an unusual state for a university robotics lab: our mobots are almost always functional. In

their basic configuration, the robots can perform many tasks; also, it is easy to add sensors and actuators to our mobile robots, allowing their use in many different applications (e.g. manipulation). We are interested in protocols for manipulation of large objects (e.g., boxes, wheeled carts) by cooperating mobile robots, particularly protocols that are asynchronous, on-line, and use no communication between mobots. We've developed a Pusher-Steerer model for cooperative manipulation, which enables two mobots to manipulate objects through complex paths. We describe and anal yze the model and describe its performance in several real experiments.

title: Election Vs. Consensus in Asynchronous Systems
abstract: It was shown in 1985 that the {\em Consensus problem} cannot be solved in an asynchronous system if even a single crash failure can occur. In this paper, we show that there are other problems that cannot be solved in an asynchronous system, and for the same intuitive reason: it is impossible to distinguish a very slow processor from a crashed processor. However, these problems are harder than Consensus, in that there are contexts in which Consensus can be solved but these other problems cannot. More precisely, the weakest failure detector that is needed to solve these problems is a Perfect Failure Detector, which is strictly stronger than the weakest failure detector that is needed to solve Consensus. We use a formulation of the Election problem as the prototype for these problems that are harder than Consensus.

title: Incorporating System Resource Information into Flow Control
abstract: Upcall-based distributed systems have become widespread in recent years. While upcall-based systems provide some obvious advantages, experiences with these systems have exposed unanticipated problems of unpredictability and inefficiency. Incorporating system resources information into flow control is essential in solving these problems. Variants of window-based flow control suitable for distributed systems are investigated. Next, message packing, which improves network bandwidth usage efficiency, and, consequently, message throughput, is presented. Finally, a back pressure mechanism which controls admission of messages into the system by blocking applications at high load is presented. The combination of the window mechanism and the back pressure mechanism provides end-to-end management of system resources. The former manages network resources, while the latter manages operating system resources. The combination maintains good throughput even under high load.

title: Preserving Privacy in a Network of Mobile Computers
abstract: Even as wireless networks create the potential for access to information from mobile platforms, they pose a problem for privacy. In order to retrieve messages, users must periodically poll the network. The information that the user must give to the network could potentially be used to track that user. However, the movements of the user can also be used to hide the user's location if the protocols for sending and retrieving messages are carefully designed. We have developed a replicated memory service which allows users to read from memory without revealing which memory locations they are reading. Unlike previous protocols, our protocol is efficient in its use of computation and bandwidth. In this paper, we will show how this protocol can be used in conjunction with existing privacy preserving protocols to allow a user of a mobile computer to maintain privacy despite active attacks.

title: A Determinizable Class of Timed Automata
abstract: We introduce the class of event-recording timed automata (ERA). An event-recording automaton contains, for every event A, a clock that records the time of the last occurrence of A. The class ERA is, on one hand, expressive enough to model (finite) timed transition systems and, on the other hand, determinizable and closed under all boolean operations. As a result, the language inclusion problem is decidable for event-recording automata. We present a translation from timed transition systems to event-recording automata, which leads to an algorithm for checking if two timed transition systems have the same set of timed behaviors. We also consider event-predicting timed automata (EPA), which contain clocks that predict the time of the next occurrence of an event. The class of event-clock automata (ECA), which contain both event-recording and event-predicting clocks, is a suitable specification language for real-time properties. We provide an algorithm for checking if a timed automaton meets a specification that is given as an event-clock automaton.

title: Achieving Critical Reliability With Unreliable Components andUnreliable Glue
abstract: Even the most aggressive quality assurance procedures yield at best probabilistic confidence in the reliability of complex systems. Distributed systems, because of their large numbers of components, are enormously complex engineering artifacts, and hence may appear to be inherently unreliable -- despite the best efforts of researchers and developers. A cellular distributed systems architecture offers the hope of drastically improving the reliability of current technologies in settings where reliability is critical. The approach combines a stateful style of distributed computing within cells with a loosely coupled probabilistic inter-cell computing model based on a probabilistic broadcast primitive. We give an implementation of this primitive, called pbcast, and demonstrate how to use it to implement this methodology. Our approach is compatible with the use of popular distributed computing and reliability technologies, while offering considerable isolation against the spread of failures among cells.

title: The Expressive Power of Clocks
abstract: We investigate the expressive power of timing restrictions on labeled transition systems. In particular, we show how constraints on clock variables together with a uniform liveness condition---the divergence of time---can express Buchi, Muller, Streett, Rabin, and weak and strong fairness conditions on a given labeled transition system. We then consider the effect, on both timed and time-abstract expressiveness, of varying the following parameters: time domain (discrete or dense), number of clocks, number of states, and size of constants used in timing restrictions.

title: Hybrid Automata with Finite Mutual Simulations
abstract: Many decidability results for hybrid automata rely upon the finite region bisimulation of timed automata [AD94]. Rectangular automata do not have finite bisimulations [Hen95], yet have many decidable verification problems [PV94,HKPV95]. We prove that every two-dimensional rectangular automaton A with positive-slope variables has a finite mutual simulation relation, which is the intersection of the region bisimulations defined by the extremal slopes of the variables of A. While the mutual simulation is infinite for two-dimensional automata with one variable taking both positive and negative slopes, it forms a regular tesselation of the plane, and therefore can be encoded by one counter. As a corollary, we obtain the decidability of model checking linear temporal logic on these automata.

title: Caching Intermediate Results for Program Improvement
abstract: A systematic approach is given for symbolically caching intermediate results useful for deriving incremental programs from non-incremental programs. We exploit a number of program analysis and transformation techniques, centered around effective caching based on its utilization in deriving incremental programs, in order to increase the degree of incrementality not otherwise achievable by using only the return values of programs that are of direct interest. Our method can be applied straightforwardly to provide a systematic approach to program improvement via caching.

title: Incremental Computation for Transformational Software Development
abstract: Given a program f and an input change $\oplus$, we wish to obtain an incremental program that computes $f(x\oplus y)$ efficiently by making use of the value of $f(x)$, the intermediate results computed in computing $f(x)$, and auxiliary information about x that can be inexpensively maintained. Obtaining such incremental programs is an essential part of the transformational-programming approach to software development and enhancement. This paper presents a systematic approach that discovers a general class of useful auxiliary information, combines it with useful intermediate results, and obtains an efficient incremental program that uses and maintains these intermediate results and auxiliary information. We give a number of examples from list processing, VLSI circuit design, image processing, {\it etc}.

title: Analyzing the Effectiveness of Extended Boolean Models in InformationRetrieval
abstract: Many extended Boolean models such as fuzzy set, p-norm, et al. have been proposed in the information retrieval literature to support ranking facility for the Boolean retrieval system. They can be explained within the same framework, and each extended Boolean model is characterized by evaluation formulas for AND and OR operations. A variety of operators have been also developed in the area of fuzzy set theory for AND and OR operations, and can be used in extended Boolean models. In this paper we analyze the behavioral aspects of various operators for AND and OR operations, and address important properties in terms of retrieval effectiveness. Our analyses show that the four properties, namely single operand dependency, negative compensation, double operand dependency and unequal importance decrease retrieval effectiveness in some circumstances. This suggests that the two properties, namely positive compensation and equal importance might help retrieval effectiveness. We also provide the experimental results that coincide with our analyses.

title: Combining Multiple Evidence from Different Properties of WeightingSchemes
abstract: It has been known that using different representations of either queries or documents, or different retrieval techniques retrieves different sets of documents. Recent work suggests that significant improvements

in retrieval performance can be achieved by combining multiple representations or multiple retrieval techniques. In this paper we propose a simple method for retrieving different documents within a single query representation, a single document representation and a single retrieval technique. We classify the types of documents, and describe the properties of weighting schemes. Then, we explain that different properties of weighting schemes may retrieve different types of documents. Experimental results show that significant improvements can be obtained by combining the retrieval results from different properties of weighting schemes.

title: EFFICIENT ACCESS TO KNOWLEDGE VIA FORWARD CHAINING TACTICS
abstract: The goal of this work is to explore efficient ways to use knowledge in interactive development of formal arguments. The challenge in automatically applying knowledge from a large knowledge base is in defining useful and tractable approximations to the deductive closure of the knowledge base. For an approximation to be useful, it must be deep in some directions. For it to be tractable, it must not be deep in all directions. Further, it must be easy to control this directedness. Thus, we need to make selective inferences from a large knowledge base that are sensitive both to its internal structure and to the query under consideration. To do this, most interactive systems employ a combination of heuristics and explicit user commands. The interaction of these two is intricate: to efficiently give hints to a heuristic prover requires developing a model of reasoning that is both efficiently implementable and easy to understand and use, i.e., fast, having a concise command language and predictable results. Rule-based specifications of approximations is the starting point for the contribution of this thesis in solving the problem described above. In this thesis, we analyze the use of rule-based forward chaining inference procedures and develop several extensions to the basic approach. We propose a new language for forward chaining tactics that can be used to specify goal-directed inference from large knowledge bases. This provides a modular approach to programming the heuristics for theorem proving. The tactic language has clean theoretical properties that make it appropriate for automated analysis and optimization. From the software engineering perspective, this thesis contains an assessment of the new software engineering approach of the theorem prover Ontic: specifying high performance theorem provers in a bottom-up logic programming framework. This perspective provides a much needed link between the Ontic project and other established research paradigms. The analysis tools developed for evaluating the forward chaining approach to obvious reasoning should have broad applications in evaluating other semi-automated approaches and systems. We also develop a language for declarative specification of control for forward chaining reasoning that is analogous to the role of LCF tacticals for specifying control in refinement-style reasoning, as embodied in Nuprl. We arrived at promising conclusions about the potential for combining

these two styles of tactic programming in such problems as the integration of decision procedures and rewriting into interactive theorem provers.

title: Protocol Composition in Horus
abstract: Horus is a communication architecture that treats a protocol as an abstract data type. Protocol layers can be stacked on top of each other in a variety of ways, at run-time. This paper starts out with describing the many classes of protocols that can be supported this way. Next, we describe the Horus object model that we designed for this technology, and the interface between the layers that makes it all work. We then present an example layer which implements a group membership protocol. Then, we look at a example stack of protocols, which provides fault-tolerant, totally ordered communication between a group of processes. We conclude with presenting some remaining challenges in our project.

title: Using Virtual Synchrony to Develop Efficient Fault TolerantDistributed Shared Memories
abstract: This paper shows how to define consistency conditions for distributed shared memories in virtually synchronous environments. Such definitions allow to develop fault tolerant implementations of distributed shared memories, in which during normal execution, operations can be performed very efficiently, and only those operations which take place during a configuration change must be delayed. Three well known consistency conditions, namely, linearizability, sequential consistency, and causal memory, are redefined for virtually synchronous environments. It is then shown how to provide efficient fault tolerant implementations for these definitions.

title: Length Normalization in Degraded Text Collections
abstract: Optical character recognition (OCR) is the most commonly used technique to convert printed material into electronic form. Using OCR, large repositories of machine readable text can be created in a short time. An information retrieval system can then be used to search through large information bases thus created. Many information retrieval systems use sophisticated term weighting functions to improve the effectiveness of a search. Term weighting schemes can be highly sensitive to the errors in the input text, introduced by the OCR process. This study examines the effects of the well known cosine normalization method in the presence of OCR errors and proposes a new, more robust, normalization method. Experiments show that the new scheme is less sensitive to OCR errors and facilitates use of more diverse basic weighting schemes. It also yields significant improvements in retrieval effectiveness over cosine normalization.

title: An Incremental Drawing Algorithm for Planar Graphs
abstract: We present a new algorithm for drawing planar graphs on the plane. It can be viewed as a generalization of the algorithm of Chrobak and Payne, which in turn, is based on an algorithm by de Fraysseix, Pach and Pollack. Our algorithm improves the previous ones in that it does not require a preliminary triangulation step; triangulation proves problematic in drawing graphs ``nicely", as it has the tendency to ruin the structure of the input graph. The new algorithm retains the positive features of the previous algorithms: It embeds a graph of n vertices on a grid of size $(2n-4)\times (n-2)$ in linear time. We have implemented the algorithm as part of a software system for drawing graphs nicely.

title: Enhancing the Nuprl Proof Development System and Applying it toComputational Abstract Algebra
abstract: This thesis describes substantial enhancements that were made to the software tools in the Nuprl system that are used to interactively guide the production of formal proofs. Over 20,000 lines of code were written for these tools. Also, a corpus of formal mathematics was created that consists of roughly 500 definitions and 1300 theorems. Much of this material is of a foundational nature and supports all current work in Nuprl. This thesis concentrates on describing the half of this corpus that is concerned with abstract algebra and that covers topics central to the mathematics of the computations carried out by computer algebra systems. The new proof tools include those that solve linear arithmetic problems, those that apply the properties of order relations, those that carry out inductive proof to support recursive definitions, and those that do sophisticated rewriting. The rewrite tools allow rewriting with relations of differing strengths and take care of selecting and applying appropriate congruence lemmas automatically. The rewrite relations can be order relations as well as equivalence relations. If they are order relations, appropriate monotonicity lemmas are selected. These proof tools were heavily used throughout the work on computational algebra. Many examples are given that illustrate their operation and demonstrate their effectiveness. The foundation for algebra introduced classes of monoids, groups, rings and modules, and included theories of order relations and permutations. Work on finite sets and multisets illustrates how a quotienting operation hides details of datatypes when reasoning about functional programs. Theories of summation operators were developed that drew indices from integer ranges, lists and multisets, and that summed over all the classes mentioned above. Elementary factorization theory was developed that characterized when cancellation monoids are factorial. An abstract data type for the operations of multivariate polynomial arithmetic was defined, and the correctness of an implementation of these operations was verified. The implementation is similar to those found in current computer algebra systems. This work was all done in Nuprl's constructive type theory. The thesis discusses the appropriateness of this foundation, and the extent to which the work relied on it.

title: Faster Possibility Detection by Combining Two Approaches
abstract: A new algorithm is presented for detecting whether a particular computation of an asynchronous distributed system satisfies $\Poss\Phi$ (read "possibly Φ"), meaning the system could have passed through a global state satisfying Φ. Like the algorithm of Cooper and Marzullo, Φ may be any global state predicate; and like the algorithm of Garg and Waldecker, $\Poss\Phi$ is detected quite efficiently if Φ has a certain structure. The new algorithm exploits the structure of some predicates Φ not handled by Garg and Waldecker's algorithm to detect $\Poss\Phi$ more efficiently than is possible with

any algorithm that, like Cooper and Marzullo's, evaluates Φ on every global state through which the system could have passed. A second algorithm is also presented for off-line detection of $\Poss\Phi$. It uses Strassen's scheme for fast matrix multiplication. The intrinsic complexity of off-line and on-line detection of $\Poss\Phi$ is discussed.

title: Dienst: Implementation Reference Manual
abstract: We describe the architecture and implementation of Dienst: a protocol and server that provides distributed document libraries over the World Wide Web. Dienst is based on a document model that incorporates unique document names, multiple document formats, and multiple document decompositions. Interoperability among Dienst servers provides the user with a single logical document collection, even though the actual collection is distributed across multiple servers. The Dienst protocol uses HTTP (the protocol of the World Wide Web) as a transport layer, making Dienst servers accessible from any WWW client. Dienst is currently used as the infrastructure for a distributed computer science technical report library by a number of U.S. universities. This document is intended as a guide for Dienst site administrators and implementors of other digital library systems. It describes the architecture of an individual server and network of Dienst servers and includes the server installation instructions. Appendices describe copyright issues and retrospective conversion of the Cornell technical report collection.

title: Estimating the Attainable Accuracy of Recursively Computed ResidualMethods
abstract: Many conjugate gradient-like methods for solving linear systems $Ax=b$ use recursion formulas for updating residual vectors, instead of computing the residuals directly. For such methods it is shown that the difference between the actual residuals and the updated approximate residual vectors generated in finite precision arithmetic depends on the machine precision ϵ and on the maximum norm of an iterate divided by the norm of the true solution. It is often observed numerically, and can sometimes be proved, that the norms of the updated approximate residual vectors converge to zero, or, at least, become orders of magnitude smaller than the machine precision. In such cases, the actual residual norm reaches the level $\ epsilon \| A \| \| x \|$ times the maximum ratio of the norm of an iterate to that of the true solution. Using exact arithmetic theory to bound the size of the iterates, we give a priori extimates of the size of the final residual for a number of algorithms.

title: Improved Curve Detection Through Decomposition of the Hough Transform
abstract: This paper describes techniques to perform fast and accurate curve detection using a variant of the Hough transform. It is shown that the Hough transform can be decomposed into many small subproble ms, where each subproblem considers only curves that pass through some subset of the points. These curves correspond to a manifold in the parameter space. This property allows the effects of localization error to be modeled more accurately than previous systems. The additional use of randomization techniques leads to efficient algorithms. The time required by this method is $O(n)$, where n is the number of edge poin ts in the image, if we are only required to find curves that are significant wit h respect to the complexity of the image. Results are given showing the detecti on of lines and circles in real images.

title: Efficient Algorithms for Optimal Video Transmission
abstract: This paper addresses the problem of sending an encoded video stream over a channel of limited bandwidth. When there is insufficient bandwidth available, some data must be dropped. For many video encodings, some data are more important than others, leading to a natural prioritization of the data. In this paper we give fast algorithms to determine a prioritization which optimizes the visual quality of the received data. By “optimized visual quality,” we mean that the expected maximum interval of unplayable frames is minimized. Our results are obtained in a model of encoded video data that is applicable to many encoding technologies. The highlight of the model is an interesting relationship between the play order and dependence order of frames. The property allows fast determination of optimal send orders by dynamic programming and is satisfied by all MPEG sequences.

title: A Complete Gentzen-style Axiomatization for Set Constraints
abstract: Set constraints are inclusion relations between expressions denoting sets of ground terms over a ranked alphabet. They are the main ingredient in set-based program analysis. In this paper we provide a Gentzen-style axiomatization for sequents $\Phi\force\Psi$, where Φ and Ψ are finite sets of set constraints, based on the axioms of termset algebra. Sequents of the restricted form $\Phi\force\bottom$ correspond to positive set constraints, and those of the more general form $\Phi\force\Psi$ correspond to systems of mixed positive and negative set constraints. We show that the deductive system is (i) complete for the restricted sequents $\Phi\force\bottom$ over standard models, (ii) incomplete for general sequents $\Phi\force\Psi$ over standard models, but (iii) complete for general sequents over set-theoretic termset algebras.

title: Newtonian Graphs, Riemann Surfaces and Computation
abstract: In this thesis we study the Newtonian graph and how to compute it. We show different applications of this computation, ranging from numerical root finding to computing the genera of algebraic Riemann surfaces.
Newton's method in the complex plane gives rise to a vector field. Certain curves of flow in this field are of particular interest as they form a connected graph, the Newtonian graph. The faces of the graph are regions corresponding to roots of the input function, and Newton's method on each region "should" converge to that root. We give a symbolic algorithm to compute the Newtonian graph for rational functions. The resulting structure can be used to improve Newton's method to guarantee convergence.
We also show how to extend the notion of Newtonian flow to a Riemann surface of an algebraic function. Again we obtain a Newtonian graph, now living on the abstract Riemann surface. We show how the graph is a tiling of the surface, and can therefore be used to compute the genus of the surface. Then we extend our earlier graph computation to cover the algebraic functions as well. All this computation is very efficient in the sense that it can all be done within the NC complexity class. This gives the first NC algorithm to compute the genus of algebraic Riemann surfaces.

title: Fast Compiled Logic Simulation Using Linear BDDs
abstract: This paper presents a new technique for compiled zero delay logic simulation, and includes extensive experiments that demonstrate its performance on standard benchmarks. Our compiler partitions the circuit into fanout-free regions (FFRs), transforms each FFR into a linear sized BDD, and converts each BDD into executable code. In our approach, the computation is sublinear in the number of variables within each partition because only one path, from root to leaf, of the BDD is executed; therefore in many cases, substantial computation is avoided. In this way, our approach gets some of the advantages of oblivious as well as demand-driven evaluation. We investigated the impact of various heuristics on performance, and based on this data, we recommend good values for design parameters. A performance improvement of up to 67% over oblivious simulation is observed for our benchmarks.

title: Lower Bounds for Fully Dynamic Connectivity Problems in Graphs
abstract: We prove lower bounds on the complexity of maintaining fully dynamic k-edge or k-vertex connectivity in plane graphs and in $(k-1)$-vertex connected graphs. We show an amortized lower bound of $\Omega (\log n / {k (\log \log n} + \log b))$ per edge insertion, deletion, or query operation in the cell probe model, where b is the word size of the machine and n is the number of vertices in G. We also show an amortized lower bound of $\Omega(\log n /(\log \log n + \log b))$ per operation for fully dynamic planarity testing in embedded graphs. These are the first lower bounds for fully dynamic connectivity problems.

title: Efficient Dynamic Network Flow Algorithms
abstract: Dynamic network flows model transportation. A dynamic network consists of a graph with capacities and transit times on its edges. Flow moves through a dynamic network over time. Edge capacities restrict the rate of flow and edge transit times determine how long each unit of flow spends traversing the network. Dynamic network flows have been studied extensively for decades.

This thesis introduces the first polynomial algorithms to solve several important dynamic network flow problems. We solve them by computing chain-decomposable flows, a new class of structured dynamic flows.

We solve the quickest transshipment problem. An instance of this problem consists of a dynamic network with several sources and sinks. Each source has a specified supply and each sink a specified demand of flow. The goal is to move the appropriate amount of flow out of each source and into each sink within the least overall time. Previously, this problem could only be solved efficiently in the special case of a single source and single sink.

Our quickest transshipment algorithm depends on efficient solutions to the dynamic transshipment problem and the lexicographically maximum dynamic flow problem. The former is a version of the quickest transshipment problem in which the time bound is specified. The latter is a maximum flow problem in a dynamic network with prioritized sources and sinks; the goal is to maximize the amount of flow leaving

each high-priority subset of sources and sinks.
We also consider the universally maximum dynamic flow problem. A universally maximum dynamic flow sends flow between a source and sink so that the sink receives flow as quickly as possible; subject to that, the source releases flow as late as possible. We describe the first polynomial algorithm to approximate a universally maximum dynamic flow within a factor of $(1+\eps)$, for any $\eps>0$. We also describe the first polynomial algorithm to compute the value of a universally maximum dynamic flow at a single specified moment of time.

title: A Subspace, Interior, and Conjugate Gradient Method for Large-ScaleBound-Constrained Minimization Problems
abstract: A subspace adaptation of the Coleman-Li trust region and interior method is proposed for solving large-scale bound-constrained minimization problems. This method can be implemented with either sparse Cholesky factorization or conjugate gradient computation. Under reasonable conditions the convergence properties of this subspace trust region method are as strong as those of its full-space version.
Computational performance on various large-scale test problems are reported; advantages of our approach are demonstrated. Our experience indicates our proposed method represents an efficient way to solve large-scale bound-constrained minimization problems.

title: Geometric Bicriteria Optimal Path Problems
abstract: A bicriteria optimal path simultaneously satisfies two bounds on two measures of path quality. The complexity of finding such a path depends on the particular choices of path quality. This thesis studies bicriteria path problems in a geometric setting using several pairs of path quality, including: path length measured according to different norms (L_{p} and L_{q}); Euclidean length within two or more classes of regions; total turn and Euclidean length; total turn and number of links; and Euclidean length and number of links.
For several cases, finding the bicriteria optimal path is shown to be NP-hard. These NP-hard cases include minimizing path length in two different norms, minimizing travel through two regions, and minimizing length and total turn. In the last case, an $O(En^{2}N^{2})$ pseudo-polynomial time algorithm to find an approximate answer is presented. In contrast, when the two measures of path quality are total turn and number of links, an $O(E^{3}n \log^{2} n)$ exact algorithm is given.
A main result of this thesis examines minimizing the Euclidean length and number of links of a path. When the geometric setting of this problem is a polygon without holes, this thesis presents an $O(n^{3}k^{3} \log(N k/ \epsilon^{1/k}))$ algorithm to find a k-link path with Euclidean length at most $1+\epsilon$ times the length of the shortest k-link path. A faster algorithm for a relaxed case, when the output path is allowed to have $2k$ links, is presented for a polygon with or without holes.
Finally, some approximation algorithms are outlined for finding a minimum link path among polyhedral obstacles.

title: Packing Messages as a Tool for Boosting the Performance of TotalOrdering Protocols
abstract: This paper compares the throughput and latency of four protocols that provide total ordering. Two of these protocols are measured with and without message packing. We used a technique that buffers application messages for a short period of time before sending them, so more messages are packed together. The main conclusion of this comparison is that message packing influences the performance of total ordering protocols under high load overwhelmingly more than any other optimization that was checked in this paper, both in terms of throughput and latency. This improved performance is attributed to the fact that packing messages reduces the header overhead for messages, the contention on the network, and the load on the receiving CPUs.

title: Exploring Query Expansion Strategies for MEDLINE
abstract: This paper evaluates the retrieval effectiveness of query expansion strategies on a MEDLINE test collection using Cornell University's Smart retrieval system. Two expansion strategies are tested on their ability to identify appropriate MeSH terms for user queries: expansion using an inter--field statistical thesaurus and expansion via pure retrieval feedback. These expansion strategies do not require prior relevance decisions. The study compares retrieval effectiveness using the original unexpanded and the alternative expanded user queries on a collection of 75 queries and 2,334 MEDLINE citations. Retrieval effectiveness is assessed using eleven point average precision scores (11-AvgP). Expansion by retrieval feedback gives the best improvement of 16.4\% over a baseline performance of 0.5169 11-AvgP. Query expansion using the inter--field thesaurus gives a significant but lower performance improvement (9.9\%) over the same baseline. This study recommends query expansion using retrieval feedback for adding MeSH search terms to a user's initial query.

title: Document Length Normalization
abstract: In the TREC collection -- a large full-text experimental text collection with widely varying document lengths -- we observe that the likelihood of a document being judged relevant by a user increases with the document length. We show that a retrieval strategy, such as the vector-space cosine match, that retrieves documents of different lengths with roughly equal probability, will not optimally retrieve useful documents from such a collection. We present a modified technique that attempts to match the likelihood of retrieving a document of a certain length to the likelihood of documents of that length being judged relevant, and show that this technique yields significant improvements in retrieval effectiveness.

title: Feature-Based Algorithms for Detecting and Classifying Scene Breaks
abstract: We describe a new approach to the detection and classification of scene breaks in video sequences. Our method can detect and classify a variety of scene breaks, including cuts, fades, dissolves and wipes,

even in sequences involving significant motion. We detect the appearance of intensity edges that are distant from edges in the previous frame. A global motion computation is used to handle camera or object motion. The algorithms we propose withstand compression artifacts such as those introduced by JPEG and MPEG, even at very high compression rates. Experimental evidence demonstrates that our method can detect and classify scene breaks that are difficult to detect with previous approaches. An initial implementation runs at approximately 2 frames per second on a Sun workstation.

title: Issues in Ordered Multicast Performance: A Simulation Study
abstract: Process groups are an increasingly popular tool for programming distributed systems. Such groups consist of collections of processes that work together to provide reliability, fault tolerance, task distribution, or some other abstraction. A combination of group actions, reliable failure detection, and ordered message delivery are used to provide group functionality. {\em Causal ordering}, one form of message ordering, is fundamental in process group systems. Its cost is therefore an important determinant of overall performance. In order to gain more insight into the behavior of causal order protocols, two simulations of process group systems were developed. The first, a detailed simulation of all system processes, groups, and interconnection networks, was used to study small systems. Using this model, a number of parameters were identified as having the greatest impact on ordered multicast performance. These parameters were used as indices to a set of precomputed probability distribution tables used by the second simulation. The second simulation focused only on key processes --- packet originators and processes in multiple overlapping groups --- and used precomputed probability tables to reduce simulation overhead. Simulations using this model showed that the delays imposed by the ordering protocols result in a tendency for packets to become "convoyed" together. Consequences are larger delays and greater system and network burstiness. We speculate that this tendency for systems to become more bursty, or less uniform, is a general principle. That is, any system which delays actions on a "microscopic" level results in burstiness at a "macroscopic" level. The more times such delays occur, the greater the degree of burstiness. Such a principle would imply that systems with this characteristic are limited in scale by the size of the largest burst that can be handled. It also suggests that protocols that minimize the number and length of delays and which optimize the handling of bursts should be used. In the context of process group systems, burstiness can be limited by minimizing the number of groups through which a packet is filtered and by protocol designs which minimize the number of delays used to control out-of-order message arrival.

title: A Consistent and Complete Deductive System for the Verification of Parallel Programs
abstract: The semantics of a simple parallel programming language is presented in two ways: deductively, by a set of Hoare-like axioms and inference rules, and operationally, by means of an interpreter. It is shown that the deductive system is consistent with the interpreter. It would be desirable to show that the deductive system is also complete with respect to the interpreter, but this is impossible since the programming language contains the natural numbers. Instead it is proven that the deductive system is complete relative to a complete proof system for the natural numbers; this result is similar to Cook's relative completeness for sequential programs. The deductive semantics given here is an extension of an incomplete deductive system proposed by Hoare. The key difference is an additional inference rule which provides for the introduction of auxiliary variables in a program to be verified.

title: Unreliable Failure Detectors for Reliable Distributed Systems
abstract: We introduce the concept of unreliable failure detectors and study how they can be used to solve Consensus in asynchronous systems with crash failures. We characterise unreliable failure detectors in terms of two properties --- completeness and accuracy. We show that Consensus can be solved even with unreliable failure detectors that make an infinite number of mistakes, and determine which ones can be used to solve Consensus despite any number of crashes, and which ones require a majority of correct processes. We prove that Consensus and Atomic Broadcast are reducible to each other in asynchronous systems with crash failures; thus the above results also apply to Atomic Broadcast. A companion paper shows that one of the failure detectors introduced here is the weakest failure detector for solving Consensus [CHT92].

title: Automatic Analysis of Hybrid Systems
abstract: Hybrid systems are real-time systems that react to both discrete and continuous activities (such as analog signals, time, temperature, and speed). Typical examples of hybrid systems are embedded systems, timing-based communication protocols, and digital circuits at the transistor level. Due to the rapid

development of microprocessor technology, hybrid systems directly control much of what we depend on in our daily lives. Consequently, the formal specification and verification of hybrid systems has become an active area of research. This dissertation presents the first general framework for the formal specification and verification of hybrid systems, as well as the first hybrid-system analysis tool--HyTech. The framework consists of a graphical finite-state-machine-like language for modeling hybrid systems, a temporal logic for modeling the requirements of the hybrid systems, and a computer procedure that verifies modeled hybrid systems against modeled requirements. The tool HyTech is the implementation of the framework using C++ and Mathematica. More specifically, our hybrid-system modeling language, Hybrid Automata, is an extension of timed automata with discrete and general continuous variables whose dynamics are governed by differential equations. Our requirement modeling language, ICTL, is a branching-time temporal logic, and is an extension of TCTL with stop-watch variables. Our verification procedure is a symbolic model-checking procedure that verifies linear hybrid automata against ICTL formulas. To make HyTech more efficient and effective, we designed and implemented model-checking strategies and abstract operators that can expedite the verification process. To enable HyTech to verify nonlinear hybrid automata, we also introduce two translations from nonlinear hybrid automata to linear hybrid automata that can be fed into HyTech for automatic analysis. We have applied HyTech to analyze more than 30 hybrid-system benchmarks. In this dissertation, we show the application of HyTech to three nontrivial hybrid systems taken from the literature.

title: Strong and Weak Virtual Synchrony in Horus
abstract: A formal definition of {\em strong virtual synchrony}, capturing the semantics of virtual synchrony as implemented in Horus, is presented. This definition has the nice property that every message is delivered within the view in which it was sent. However, it is shown that in order to implement strong virtual synchrony, the application program has to block messages during view changes. An alternative definition, called {\em weak virtual synchrony}, which can be implemented without blocking messages, is then presented. This definition still guarantees that messages will be delivered within the view in which they were sent, only that it uses a slightly weaker notion of what the view in which a message was sent is. An implementation of weak virtual synchrony that does not block messages during view changes is developed, and it is shown how to use a system that provides weak virtual synchrony even when strong virtual synchrony is actually needed. To capture additional ordering requirements, the definition of {\em ordered virtual synchrony} is presented. Finally, it is discussed how to extend the definitions in order to cope with the fact that a process can become a member of more than one group.

title: Processor Controlled Off-Processor I/O
abstract: The performance of modern RISC processors on operating system code is well below application code performance. The kernel code implementing communication services across the network is not an exception. Modern networking technologies are characterized by a small packet size, which further increases the communication overhead. We took the approach of removing the kernel layer from the cross-machine communication path while still providing protection. The presence of a programmable communication processor on the network adapter made this experiment possible. The firmware running on the communication processor implements a Virtual Communication Machine (VCM); applications communicate with the VCM

through shared memory without having to switch to kernel mode. Data is transferred directly between application buffers and the network without any intermediate buffering in the user or kernel spaces. The VCM architecture makes this possible; in particular, the VCM can be programmed to access any location in the address space of an application. The main processor controls the communication but it is not directly involved with it; as a consequence, the overhead on the main processor is very low. The design not only provides very low latencies, but also minimizes the effect of communication on the main processor data caches. We implemented the datagram subset of the Berkeley sockets interface on top of the VCM interface and integrated it with a user-level thread package. Multicast capabilities were added to the interface. Performance measured at both the VCM and socket layers is presented.

title: THE DESIGN AND IMPLEMENTATION OF A PRIVATE MESSAGE SERVICE FOR MOBILE COMPUTERS
abstract: Even as wireless networks create the potential for access to information from mobile platforms, they pose a problem for privacy. In order to retrieve messages, users must periodically poll the network. The information that the user must give to the network could potentially be used to track that user. However, the movements of the user can also be used to hide the user's location if the protocols for sending and retrieving messages are carefully designed. In this thesis, we will present a protocol for a replicated memory service which allows users to read from memory without revealing which memory locations they are reading. Unlike previous protocols, this protocol is efficient in its use of computation and bandwidth. We will then show how this protocol can be used in conjunction with existing privacy preserving protocols to allow a user of a mobile computer to maintain privacy despite active attacks. Allowing users to retrieve messages anonymously introduces a new problem. In order to limit memory usage, it is necessary to remove old messages from the system. However, since users may become disconnected from the network for periods of time, it is important that the system hold onto messages until they have been retrieved by their intended recipients. The result is a conflict between the system's need for information and users' desire for privacy. We will present the design of a vacation service which we have developed which stores messages for users which are disconnected which does not require users to reveal any private information. Finally, we will describe the implementation of the private message service and discuss the performance estimates that we derived for the system based on experimental results. As we will show, the potential throughput of the private message service is reasonable.

title: What's Decidable About Hybrid Automata?
abstract: Hybrid automata model systems with both digital and analog components, such as embedded control programs. Many verification tasks for such programs can be expressed as reachability problems for hybrid automata. By improving on previous decidability and undecidability results, we identify the precise boundary between decidability and undecidability of the reachability problem for hybrid automata. On the positive side, we give an (optimal) PSPACE reachability algorithm for the case of initialized rectangular automata, where all analog variables follow trajectories within piecewise-linear envelopes and are reinitialized whenever the envelope changes. Our algorithm is based on the construction of a timed automaton that contains all reachability information about a given initialized rectangular automaton. The translation has practical significance for verification, because it guarantees the termination of symbolic procedures for the reachability analysis of initialized rectangular automata. The translation also preserves the ω-languages of initialized rectangular automata with bounded nondeterminism. On the negative side, we show that several slight generalizations of initialized rectangular automata lead to an undecidable reachability problem. In particular, we prove that the reachability problem is undecidable for timed automata augmented with a single stopwatch.

title: SplitThreads - Split-C Threads
abstract: SplitThreads are enhancements to Split-C by user level non pre-emptive threads. The primary motivation for SplitThreads comes from the fact that the SPMD paradigm of Split-C is a limitation for some important problems. At the same time, Split-C is very efficient and is tunable for good performance. Other related approaches such as Nexus have a large amount of overhead in providing threads capability. This paper presents the addition of a lightweight user-level threads package to Split-C. The performance numbers obtained show significant improvement over existing comparable approaches such as Nexus. The underlying thread library core is QuickThreads. QuickThreads provides minimal support for thread management. Additional functionality is provided by SplitThreads on top of this core. Finally, SplitThreads provides higher level user objects such as I-structures and M-structures

title: INEXACT REFLECTIVE NEWTON METHODS FOR LARGE-SCALE OPTIMIZATION SUBJECT TOBOUND CONSTRAINTS
abstract: This thesis addresses the problem of minimizing a large-scale nonlinear function subject to simple bound constraints. The most popular methods to handle bound constrained problems, active-set methods, introduce a combinatorial aspect to the problem. For these methods, the number of steps to converge may be related to the number of constraints. For large problems, this behavior is particularly detrimental. Reflective Newton methods avoid this problem by staying strictly within the constrained region. As a result, these methods have strong theoretical properties. Moreover, they behave experimentally like an unconstrained method: the number of steps to a solution is not strongly correlated with problem size. In this thesis, we

discuss the reflective Newton approach and how it can be combined with inexact Newton techniques, within a subspace trust-region method, to efficiently solve large problems. Two algorithms are presented. The first uses a line search as its globalizing strategy. The second uses a strictly trust-region approach to globally converge to a local minimizer. Global convergence and rate of convergence results are established for both methods. We present computational evidence that using inexact Newton steps preserves the properties of the reflective Newton methods: the iteration counts are as low as when "exact" Newton steps are used. Also, both the inexact and exact methods are robust when the starting point is varied. Furthermore, the inexact reflective Newton methods have fast convergence when negative curvature is encountered, a trait not always shared by similar active-set type methods. The role of negative curvature is further explored by comparing the subspace trust-region approach to other common approximations to the full-space trust-region problem. On problems where only positive curvature is found, these trust-region methods differ little in the number of iterations to converge. However, for problems with negative curvature, the subspace method is more effective in capturing the negative curvature information, resulting in faster convergence. Finally a parallel implementation on the IBM SP2 is described and evaluated; the scalability and efficiency of this implementation are shown to be as good as the matrix-vector multiply routine it depends on.

title: Classification and Lower Bounds for MEMS Arrays and Vibratory Parts Feeders:What Programmable Vector Fields Can (and Cannot) Do --- Part I
abstract: Programmable vector fields can be used to control a variety of flexible planar parts feeders. These devices can exploit exotic actuation technologies such as arrayed, massively-parallel microfabricated motion pixels or transversely vibrating (macroscopic) plates. These new automation designs promise great flexibility, speed, and dexterity---we believe they may be employed to orient, singulate, sort, feed, and assemble parts. However, since they have only recently been invented, programming and controlling them for manipulation tasks is challenging. By chaining together sequences of vector fields, the equilibrium states of a part in the field may be cascaded to obtain a desired final state. The resulting strategies require no sensing and enjoy efficient planning algorithms. This paper begins by describing our experimental devices. In particular, we describe our progress in building the {\sc M-Chip} (\underline{m}anipulation \underline{chip}), a massively parallel array of programmable micro-motion pixels. As proof of concept, we demonstrate a prototype {\sc M-Chip} containing over 11,000 silicon actuators in one square inch. Both the {\sc M-Chip}, as well as macroscopic devices such as transversely vibrating plates, may be programmed with vector fields, and their behavior predicted and controlled using our {\em equilibrium analysis}. We demonstrate lower bounds (i.e., impossibility results) on what the devices {\em cannot} do, and results on a classification of control strategies yielding design criteria by which well-behaved manipulation strategies may be developed. We provide sufficient conditions for programmable fields to induce well-behaved equilibria on every part placed on our devices. We define {\em composition operators} to build complex strategies from simple ones, and show the resulting fields are also well-behaved. We discuss whether fields outside this class can be useful and free of pathology.

title: New and Improved Manipulation Algorithms for MEMS Arrays and Vibratory PartsFeeders: What Programmable Vector Fields Can (and Cannot) Do --- Part II

abstract: This paper explores how to use programmable vector fields to control flexible planar parts feeders. For a description of these devices and their actuation technology, see our companion paper, Part~I~\cite{BohringerDonaldMacDonald96b}\ifDRAFT{}\else{, also submitted to ICRA}\fi . When a part is placed on our devices, the programmed vector field induces a force and moment upon it. Over time, the part may come to rest in a dynamic equilibrium state. By chaining together sequences of vector fields, the equilibria may be cascaded to obtain a desired final state. By analyzing and constraining the equilibria of programmable vector fields, we can generate and execute plans to orient and sort parts. These plans require no sensing. This paper describes new manipulation algorithms using the tools developed in Part~I~\cite{BohringerDonaldMacDonald96b}. In particular, we improve existing planning algorithms by a quadratic factor, and the plan-length by a linear factor. Using our new and improved strategies, we show how to simultaneously orient and pose any part, without sensing, from an arbitrary initial configuration. We relax earlier dynamic and mechanical assumptions to obtain more robust and flexible strategies. Finally, we consider parts feeders that can only implement a very limited "vocabulary" of vector fields (as opposed to the pixel-wise programmability assumed above). We show how to plan and execute parts-posing and orienting strategies for these devices, but with a significant increase in planning complexity and some sacrifice in completeness guarantees. We discuss the tradeoff between mechanical complexity and planning complexity.

title: DESIGN, FABRICATION, AND CHARACTERIZATION OF SINGLE CRYSTAL SILICON LATCHINGSNAP FASTENERS FOR MICRO ASSEMBLY
abstract: A snap fastener is a deformable device consisting of a pair of mating surfaces that "snap" together during assembly. Because of the simple, linear assembly motion, such latching micro fasteners have a wide range of applications in micro assembly tasks, e.g.\ for devices with multiple or layered components, or micro opto-mechanical plugs. At the micro scale, conventional types of fasteners like screws and hinges are unlikely to work due to present fabrication constraints and large friction forces. Micro snap fasteners also have great potential to be used as sensors with memory.

title: Sensorless Manipulation Using Transverse Vibrations of a Plate
abstract: The existing industrial parts feeders move the parts through a sequence of mechanical filters that reject parts in unwanted orientations. In this paper we develop a new setup that uses a different vibratory mechanism to systematically manipulate parts, by actively orienting and localizing them. The idea is to generate and change dynamic modes for a plate by varying the applied frequency of oscillation. Depending on the node shapes of the plate for these frequencies, the position and orientation of the parts can be controlled. We develop an analysis of the underlying dynamics, and show that it can be used to predict the behavior of objects placed on the vibrating plate. Using this analysis, we propose that the applied frequencies can be automatically sequenced to obtain a "sensorless" strategy for manipulating a given object.

title: Selective Text Traversal
abstract: In information retrieval and text processing, the size of the available databases and text collections has grown enormously in the past few years, and users find it difficult to cope with the amount of text that is potentially of interest. As a result, there is growing interest in approaches capable of breaking down large texts into smaller constituent units, and in using short text passages for storage and retrieval purposes. Methods are described in this study for identifying important text passages in large texts, and suggestions are made for implementing useful text reading and text traversal strategies that provide selective text access in accordance with user needs. Some evaluation results for selective text access are appended.

title: Approximating Perfect Failure Detectors in Asynchronous Distributed Systems
abstract: Systems that provide group membership services (e.g., Isis) can be used
to solve many canonical problems in distributed systems, such as Consensus and Leader Election. However, solving these problems has been shown to require {\em failure detectors} of various strengths, all of which are impossible to implement in an asynchronous system. It has been shown that it is possible to solve Consensus in an asynchronous distributed system using a very weak failure detector. However, existing group membership systems do not appear to implement this type of failure detector. Furthermore, there are other problems that can be solved with group membership services, such as Leader Election, that are harder than Consensus and cannot be solved without a perfect failure detector. This leads to an apparent contradiction: how can provably impossible problems be solved in existing group membership systems? In this dissertation, we investigate {\em approximations} to perfect failure detectors in order to obtain acceptable and practical solutions to otherwise-impossible problems such as Election. We argue that approximating a perfect failure detector yields approximate solutions to these problems, and define a notion of approximation that yields solutions that are useful in practice. We give a formal specification of an approximately-perfect failure detector, give two protocols that implement our approximation, and derive upper bounds on the number of tolerable failures for any such protocol. The approximately-perfect failure detector presented in this dissertation is similar to that used in Isis; this implies that the failure detector implemented in group membership services such as Isis are actually approximately-perfect failure detectors, and that the resulting solutions to Consensus, Election, and other problems are approximate solutions. Furthermore, the protocols that implement our specification are very simple and can be easily implemented. Such an implementation could be used in existing or future group membership services, or by other systems programmers for whom group membership services are not necessary but for whom failure detection would be useful.

title: Incremental Computation: A Semantics-Based Systematic Transformational Approach
abstract: Incremental computation takes advantage of repeated computations on inputs that differ slightly from one another, computing each new output incrementally by making use of the previous output rather than from scratch. This thesis concerns the theory, design, and implementation of a general approach to incremental computation. It also elucidates the essence of improving the efficiency of computations by relating it to incremental computation. Our general approach allows incremental computation to be obtained systematically from non-incremental computation and program efficiency to be systematically improved. This research focuses on identifying the fundamentals of efficient incremental computation out of domain-specific properties and language-specific features, devising a general framework that accommodates these fundamentals, and developing a systematic approach based on the framework that exploits program semantics. Three fundamental aspects of incremental computation are identified: avoiding repeated identical computations, caching useful intermediate results, and discovering appropriate auxiliary information. Given a program f and an operation $\oplus$, an incremental program is developed to compute $f(x\ oplus y)$ efficiently by using $f(x)$, the intermediate results computed in computing $f(x)$, and auxiliary information about x that can be inexpensively maintained. The approach in this thesis is formalized for a simple functional language, but the underlying principles also apply to other programming languages. It exploits program semantics to discover incrementality that is not directly embedded in primitive operators and takes into consideration properties of application domains as well. It is composed of step-wise program analysis and transformation modules that can, for the most part, be mechanized. Since every non-trivial computation proceeds by iteration (or recursion), the approach is used straightforwardly for achieving efficient computation in general, by computing each iteration incrementally using an appropriate incremental program. This method is applied to problems in interactive systems, optimizing compilers, transformational program development, {\it etc}. The design and implementation of a prototype system, CACHET, for obtaining incremental programs is also described.

title: A Newton Acceleration of the Weiszfeld Algorithm for Minimizing the Sum ofEuclidean Distances
abstract: The Weiszfeld algorithm for continuous location problems can be considered as an iteratively reweighted least squares method. It exhibits linear convergence. In this paper, a Newton type algorithm with similar simplicity is proposed to solve a continuous multifacility location problem with Euclidean distance measure. Similar to the Weiszfeld algorithm, at each iteration the main computation can be solving a weighted least squares problem. A Cholesky factorization of a symmetric positive definite band matrix, typically with a relatively small band width (e.g., a band width of two for a Euclidean location problem on a plane) is required. This new algorithm can be regarded as a Newton acceleration to the Weiszfeld algorithm with fast global and local convergence. The simplicity and efficiency of the proposed algorithm makes it particularly suitable for large-scale Euclidean location problems and parallel implementation. Computational experience also suggests that the proposed algorithm performs remarkably well in the presence of degeneracy and near degeneracy. In addition, it is proven to be globally convergent. Although the local convergence analysis is still under investigation, computation results suggest that it is typically superlinearly convergent.

title: Deciding in Partitionable Networks
abstract: Motivated by Chandra and Toueg's work, we study decision protocols in a model that closely approximates "real" distributed systems. Our results show how the weakest failure detector and associated consensus algorithm can be adapted to a network in which omission failures can occur during periods when processes suspect one-another as faulty. For protocols in which a majority subset of the participants can reach decisions on behalf of the system as a whole, we also characterize a series of stages that necessarily arise during execution. Jointly, these findings establish a direct relationship between an extended version of the three-phase commit protocol, which makes progress even when a traditional three-phase commit would block, and the consensus protocol of Chandra and Toueg. Although we do not explore the linkage here, our results should also be applicable to other agreement protocols for systems of this sort, such as leader election and dynamic group membership.

title: Automatic Text Decomposition Using Text Segments and Text Themes
abstract: With the widespread use of full-text information retrieval, passage-retrieval techniques are becoming increasingly popular. Larger texts can then be replaced by important text excerpts, thereby simplifying the retrieval task and improving retrieval effectiveness. Passage-level evidence about the use of words in local contexts is also useful for resolving language ambiguities and improving retrieval output. Two main text decomposition strategies are introduced in this study, including a chronological decomposition into {\em text segments}, and semantic decomposition into {\em text themes}. The interaction between text segments and text themes is then used to characterize text structure, and to formulate specifications for information retrieval, text traversal, and text summarization.

title: Pseudospectra of linear operators
abstract: The advent of ever more powerful computers has brought with it a new way of conceiving some of the fundamental eigenvalue problems of applied mathematics. If a matrix or linear operator A is far from normal, its eigenvalues or more generally its spectrum may have little to do with its behavior as measured by quantities such as $\|A^n\|$ or $\EtA$.\ \ More may be learned by examining the sets in the complex plane known as the {\it pseudospectra} of A, defined by level curves of the norm of the resolvent, $\Resz$. Five years ago, the author published a paper that presented computed pseudospectra of thirteen highly non-normal matrices arising in various applications. Since that time, analogous computations have been carried out for

differential and integral operators. This paper, a companion to the earlier one, presents ten examples, each chosen to illustrate one or more mathematical or physical principles.

title: Pivoted Document Length Normalization
abstract: Document length normalization is an important aspect of term weight assignment in an automatic information retrieval system. In this study, we observe that a normalization scheme that retrieves documents of all lengths with similar chances as their likelihood of relevance will outperform another scheme which retrieves documents with chances very different from their likelihood of relevance. We show that the retrieval probabilities for a particular normalization method deviate systematically from the relevance probabilities across different collections. We present pivoted normalization a technique that can be used to reduce the gap between the relevance and the retrieval probabilities. Training pivoted normalization on one collection, we can successfully use it on other (new) text collections, yielding a robust, collection independent normalization technique. We use the idea of pivoting with the well known cosine normalization scheme. We point out some shortcomings of the cosine normalization function and present two new normalization functions --- pivoted unique normalization and pivoted byte size normalization.

title: Faster Algorithms for the Nonemptiness of Streett Automata and forCommunication Protocol Pruning
abstract: This paper shows how a general technique, called {\it lock-step search}, developed for dynamic graph algorithms, can be used to improve the running time of two problems arising in program verification and communication protocol design. (1) We consider the {\it nonemptiness problem for Streett automata}: We are given a directed graph $G=(V,E)$ with $n=|V|$ and $m=|E|$, and a collection of pairs of subsets of vertices, called {\em Streett pairs}, $\langle L_i, U_i \rangle, i= 1..k$. The question is whether G has a cycle (not necessarily simple) which, for each $1 \leq i \leq k$, either contains no vertex from L_i or contains a vertex of U_i. Let $b= \sum_{i=1..k} |L_i|+|U_i|$. The previously best algorithm takes time $O((m+ b)\ min\{n,k\})$. We present an algorithm that takes time $O(m \min \{ \sqrt{m \log n}, k, n\} + b \min \{\log n, k\})$. (2) In {\it communication protocol pruning} we are given a directed graph $G=(V,E)$ with l special vertices. The problem is to efficiently maintain the strongly-connected components of the special vertices on a restricted set of edge deletions. Let m_i be the number of edges in the strongly connected component of the ith special vertex. The previously best algorithm repeatedly recomputes the strongly-connected components which leads to a running time of $O(\sum_i m_i^2)$. We present an algorithm with time $O(\ sqrt{l}\sum_i m_i^{1.5})$.

title: Improved Sampling with Applications to Dynamic Graph Algorithms
abstract: We state a new sampling lemma and use it to improve the running time of dynamic graph algorithms. For the dynamic connectivity problem the previously best randomized algorithm takes expected time $O(\ log^3n)$ per update, amortized over $\Omega(m)$ updates. Using the new sampling lemma, we improve its running time to $O(\log^2n)$. There exists a lower bound in the cell probe model for the time per operation of $\Omega(\log n/\log \log n)$ for this problem. Similarly improved running times are achieved for the following dynamic problems: (1) $O(\log^3 n)$ to maintain the bridges in a graph (the 2-edge connectivity problem); (2) $O(k \log^2n)$ to maintain a minimum spanning tree in a graph with k different weights (the k-weight minimum spanning tree problem); (3) $O(\log^2n \log U/\epsilon')$ to maintain a spanning tree whose weight is a $(1+\epsilon')$-approximation of the weight of the minimum spanning tree, where U is the maximum weight in the graph (the $(1+\epsilon')$-approximate minimum spanning tree problem); and (4) $O(\log^2 n)$ to test if the graph is bipartite (the bipartiteness-testing problem).

title: Metatheory of the π-Calculus
abstract: Milner's {π}-calculus is a very influential process algebra in which communication channels are first-class objects. One of the basic concepts in the language is the transmission of one channel along another. This leads to immensely powerful programming techniques, which have been used for modelling things from cellular telephones to object-oriented languages. However, the {π}-calculus lacks many operations, such as broadcasting a value to many processes, interrupting processes, checkpointing, and even such basics as sequencing and \t{while}-loops in full generality. Adding all useful operations to the {π}-calculus would make it unusably large and complex. We thus propose a \e{rule format}, called \metapi. The {π}-calculus, and a vast range of other calculi treating channels as first-class data, can be expressed with {\metapi} rules. Any operations defined by {\metapi} rules have the same essential theory as the {π}-calculus. For example, all such operations respect the appropriate notion of strong bisimulation. Furthermore, the {π}-calculus, and all the operations in the previous paragraph, have {\metapi} equivalents. {\metapi} describes the heart of the {π}-calculus without prejudice towards the particular communication mechanisms of the calculus, and thus gives a general framework for working with {π}-like calculi. Further, it can be argued that the {\metapi} rule format is the most general of its kind, in the sense that any obvious extensions to the format would cause important language properties to be violated.

title: Fault-tolerant Wait-free Shared Objects
abstract: Wait-free implementations of shared objects tolerate the failure of processes, but not the failure of base objects from which they are implemented. We consider the problem of implementing shared objects that tolerate the failure of both processes and base objects. We identify two classes of object failures: responsive and non-responsive. With responsive failures, a faulty object responds to every operation, but its responses may be incorrect. With non-responsive failures, a faulty object may also "hang" without responding. In each class, we define crash, omission, and arbitrary modes of failure. We show that all responsive failure modes can be tolerated. More precisely, for all responsive failure modes F, object types T, and t, we show how to implement a shared object of type T which is t-tolerant for F. Such an object remains correct and wait-free even if up to t base objects fail according to F. In contrast to responsive failures, we show that even the most benign non-responsive failure mode cannot be tolerated. We also show that randomization can be used to circumvent this impossibility result. Graceful degradation is a desirable property of fault-tolerant implementations: the implemented object never fails more severely than the base objects it is derived from, even if all the base objects fail. For several failure modes, we show whether this property can be achieved, and, if so, how.

title: Connectionist Networks for Feature Indexing and Object Recognition
abstract: Feature indexing techniques are promising for object recognition because of their ability to eliminate many feature set matches from consideration without much computation. This work exploits another property of such techniques. They have inherently parallel structure and connectionist network formulations are easy to develop. Once indexing has been performed, a voting scheme such as geometric hashing [Lamdan et al. 1990] can be used to generate object hypotheses in parallel. We give a framework for the connectionist implementation for such indexing and recognition techniques. With sufficient processing elements, recognition can be performed in a small number of time steps. The number of processing elements necessary to achieve peak performance and the fan-in/fan-out required for the processing elements is determined. These techniques have been simulated on a conventional architecture with good results.

title: The Object Group Design Pattern
abstract: This paper describes ``Object Group'', an object behavioral pattern for group communication and fault-tolerance in distributed systems. The Object Group pattern allows the implementation of replicated objects, of load sharing, and of efficient multicast communication over protocols like IP-multicast and UDP-broadcast. Application areas of the pattern are fault-tolerant client/server systems, groupware, and parallel text retrieval engines. Events within an Object Group honor the Virtual Synchrony model. Owing to Virtual Synchrony, the size of an object group can be varied at run-time, while client applications are interacting with the object. A replicated state remains consistent in spite of objects entering and leaving the group dynamically and in spite of failures. The Object Group pattern has been implemented in the Electra and in the Orbix+Isis CORBA Object Request Broker.

title: Performance of the Horus Asynchronous Group Communication System under HighLoad
abstract: Horus is an asynchronous group communications system designed to support a variety of distributed and parallel applications. This paper reports the performance of continuous $n \times n$ multicasts for a Horus protocol stack that provides fully reliable communication over Ethernet supporting IP multicast. This communication pattern not only is highly demanding from the communications point of view, but also is common for an important class of distributed applications. Specific findings reported in this paper are: providing reliability is expensive under high loss; the cost of providing full reliability is modest compared to that of providing simple reliability; the lack of receivers' resources contributes to high loss; the lack of synchronization among group members also contributes to high loss; and controlling the send rate based on receivers' resource availability is a promising method for maintaining high throughput under high load.

title: A Fault-Tolerant CORBA Name Server
abstract: OMG CORBA applications require a distributed naming service in order to install and to retrieve object references. High availability of the naming service is important as most CORBA applications need to

access it at least once during their lifetime. Unfortunately, the OMG standards do not deal with availability issues, and the naming services of many of the commercially available CORBA object request brokers introduce single points of failure. In this paper we describe the design and implementation of a replicated, highly-available CORBA name server that adheres to the OMG Common Object Services Specification. Our naming service can be replicated at run-time, while many applications are installing and retrieving object references. We compare our approach with the approaches taken by the ILU, NEO, Orbix, and DOME object request brokers. The performance of our name server is measured for various replication degrees.

title: Stereo Matching with Non-Linear Diffusion
abstract: One of the central problems in stereo matching (and other image registration tasks) is the selection of optimal window sizes for comparing image regions. This paper addresses this problem with some novel algorithms based on iteratively diffusing support at different disparity hypotheses, and locally controlling the amount of diffusion based on the current quality of the disparity estimate. It also develops a novel Bayesian estimation technique which significantly outperforms techniques based on area-based matching (SSD) and regular diffusion. We provide experimental results on both synthetic and real stereo image pairs.

title: Some Notes on Rational Spaces
abstract: Set constraints are inclusions between expressions denoting set of ground terms over a finitely ranked alphabet Σ. Rational spaces are topological spaces obtained as spaces of runs of topological Σ-hypergraphs. They were introduced by Kozen in \cite{K95a}, where the topological structure of the spaces of solutions to systems of set constraints was given in terms of rational spaces. In this paper we continue the investigation of rational spaces. We give a Myhill-Nerode like characterization of rational points, which in turn is used to re-derive results about the rational points of finitary rational spaces. We define congruences on Σ-hypergraphs, investigate their interplay with the Myhill-Nerode characterization, and finally we determine the computational complexity of some decision problems related to rational spaces.

title: Understanding the Message Logging Paradigm for Masking Process Crashes
abstract: Message logging is a popular technique for building systems that can tolerate process crashes and transient channel failures. The technique, which was first developed in the mid-80s, is popular because message-logging protocols are relatively simple and require process replication only when a process fails. Surprisingly, however, very little attention has been given to the formal specification of the consistency property that these protocols implement in order to be able to recover failed processes to a consistent state. This dissertation presents the first such formal specification. From this specification, the two major classes of message-logging protocols, namely {\em optimistic} and {\em pessimistic}, are characterized. A third and new class of message-logging protocols, called {\em causal}, is introduced. A notion of optimality, based on three important performance metrics, is proposed, and it is shown that optimal implementations of causal

message-logging protocols exist. In particular, it is shown that causal message-logging protocols combine the positive aspects of optimistic and pessimistic message logging. A subclass of causal message-logging protocols, called {\em family-based logging}, is developed. Family-based logging protocols are optimal and have the additional attractive characteristic that the smaller the maximum number of concurrent failures, the lower their overhead. Furthermore, several compression techniques can be used to reduce this overhead. Finally, it is shown that family-based logging protocols can be implemented in order to take advantage of the different patterns of communication that systems exhibit.

title: Adding the Everywhere Operator to Propositional Logic
abstract: Sound and complete modal propositional logic C is presented, in which "P" has the interpretation "P is true in all states". The interpretation is already known as the Carnapian extension of S5. A new axiomatization for C provides two insights. First, introducing an inference rule "textual substitution" allows seamless integration of the propositional and modal parts of the logic, giving a more practical system for writing formal proofs. Second, the two following approaches to axiomatizing a logic are shown to be not equivalent: (i) give axiom schemes that denote an infinite number of axioms and (ii) write a finite number of axioms in terms of propositional variables and introduce a substitution inference rule.

title: A Transparent Light-Weight Group Service
abstract: Virtual synchrony, also known as view synchrony, has proven to be a powerful paradigm to build distributed applications. Informally, virtual synchrony provides to each process group membership information in the form of {\em views} and guarantees that all processes that install a given view have delivered the same set of messages from the previous view. Implementations of virtual synchrony usually require the use of failure detectors and failure recovery protocols. There is a range of applications that require the use of a large number of groups with the same membership. In such applications, significant performance gains can be attained if these groups share the resources required to provide virtual synchrony. A service that maps user groups into instances of a virtually synchronous implementation is called a Light-Weight Group Service. This paper proposes a new design for the Light-Weight Group Service protocols that circumvents some of the limitations of previous approaches. As a test case, the new protocols were implemented in the Horus system, although the underlying principles can be applied to other architectures as well. The paper also presents performance results from this implementation.

title: MultiMATLAB: MATLAB on Multiple Processors
abstract: MATLAB, a commercial product of The MathWorks, Inc., has become one of the principal languages of desktop scientific computing. A system is described that enables one to run MATLAB conveniently on multiple processors. Using short, MATLAB-style commands like Eval, Send, Recv, Bcast, Min, and Sum, the user operating within one MATLAB session can start MATLAB processes on other machines and then pass commands and data between between these various processes in a fashion that maintains MATLAB's traditional user-friendliness. Multi-processor graphics is also supported. The system currently runs under MPICH on an IBM SP2 or a network of Unix workstations, and extensions are planned to networks of PCs. MultiMATLAB is potentially useful for education in parallel programming, for prototyping parallel algorithms, and for fast and convenient execution of easily parallelizable numerical computations on multiple processors.

title: State Equivalences for Rectangular Hybrid Automata
abstract: Three natural equivalence relations on the infinite state space of a hybrid automaton are language equivalence, simulation equivalence, and bisimulation equivalence. When one of these equivalence relations has a finite quotient, certain model checking and controller synthesis problems are decidable. When bounds on the number of equivalence classes are obtained, bounds on the running times of model checking and synthesis algorithms follow as corollaries. We characterize the time-abstract versions of these equivalence relations on the state spaces of rectangular hybrid automata (RHA), in which each continuous variable is a clock with bounded drift. These automata are useful for modeling communications protocols with drifting local clocks, and for the conservative approximation of more complex hybrid systems. Of our two main results, one has positive implications for automatic verification, and the other has negative implications. On the positive side, we find that the (finite) language equivalence quotient for RHA is coarser than was previously known by a multiplicative exponential factor. On the negative side, we show that simulation equivalence for RHA is equality (which obviously has an infinite quotient). Our main positive result is established by analyzing a subclass of timed automata, called one-sided timed automata (OSA), for which the language equivalence quotient is coarser than for the class all of timed automata. An exact characterization of language equivalence for OSA requires a distinction between synchronous and asynchronous definitions of (bi)simulation: if time actions are silent, then the induced quotient for OSA is coarser than if time actions are visible.

title: SCOM: A Security and Privacy Layer for Horus
abstract: A large number of distributed applications will soon be implemented for which the inclusion of some form of security will be important. While the programmers who design these applications may have expertise in the application area, they most likely will not be experts in the areas of distributed computing or security. In both of these areas, a firm knowledge of the subject is necessary in order to avoid subtle, hard to detect flaws in design. The Horus system was created to enable the design and implementation of distributed applications. The ultimate goal of this work is to allow for the implementation of efficient distributed applications while hiding many of the problems associated with the design of such applications from the

applications programmer. In this paper, we describe work we have done to facilitate the implementation of secure distributed applications on top of the Horus system.

title: An Object Recognition System for Complex Imagery that Models theProbability of a False Positive
abstract: This paper describes an object recognition system for use in complex imagery that can perform recognition adaptively by setting the matching threshold such that the probability of a false positive is low. In order to accurately model small, irregularly shaped objects, we represent the objects using dense sets of edge pixels with associated local orientations. Three-dimensional objects are modeled by a set of two-dimensional views of the object. We allow translation, rotation, and scaling of the views to approximate full three-dimensional motion of the object. We use a version of the Hausdorff measure to determine which positions of an object model are good matches to an image. These positions are determined efficiently through the examination of a hierarchical cell decomposition of the transformation space, which allows large volumes of the space to be pruned quickly. Additional techniques are used to decrease the computation time of the method when matching is performed against a catalog of object models. We then describe a new model of the matching process that allows the probability of a false positive to be estimated efficiently at run-time. Finally, we give results of this system recognizing object in infrared and intensity images.

title: Matrix Behaviour, Unitary Reducibility, and Hadamard Products
abstract: The question investigated here is: if two matrices A and B in $\CNN$ have identical behaviour in a unitarily invariant norm $\norm{\cdot}$, \ie,\ $\norm{p(A)} = \norm{p(B)}$ for every polynomial p with complex coefficients, what properties do A and B have in common? After a preliminary result about eigenvalues, it is shown with a mildly restrictive assumption that if A is unitarily reducible, so is B. A theorem is proved about Hadamard products of the form $H\circ\invt{H}$, where H is Hermitian positive definite. Finally, an example is produced where A and B have identical behaviour in the Frobenius norm, but are not related to each other in any simple way.

title: Optimal Control Dependence Computation and the Roman Chariots Problem
abstract: The control dependence relation plays a fundamental role in program restructuring and optimization. The usual representation of this relation is the control dependence graph (CDG), but the size of the CDG can grow quadratically with the input program, even for structured programs. In this paper, we introduce the augmented postdominator tree, APT, a data structure which can be constructed in space and time proportional to the size of the program, and which supports enumeration of a number of useful control-dependence sets in time proportional to their size. Therefore, APT provides an optimal representation of control dependence. Specifically, the APT data structure supports enumeration of the set cd(e), which is the set of statements control dependent on control-flow edge e, of the set conds(w), which is the set of edges on which statement w is dependent, and of the set cdeq(w), which is the set of statements having the same control dependences as w. Technically, APT can be viewed as a factored representation of the CDG where queries are processed using an approach known as filtered search.

title: The Theory of Rectangular Hybrid Automata
abstract: A {\em hybrid automaton\/} consists of a finite automaton interacting with a dynamical system. Hybrid automata are used to model embedded controllers and other systems that consist of interacting discrete and continuous components. A hybrid automaton is {\em rectangular\/} if each of its continuous variables~x satisfies a nondeterministic differential equation of the form $a\le\frac{dx}{dt}\le b$, where a and~b are rational constants. Rectangular hybrid automata are particularly useful for the analysis of communication protocols in which local clocks have bounded drift, and for the conservative approximation of systems with more complex continuous behavior. We examine several verification problems on the class of rectangular hybrid automata, including reachability, temporal logic model checking, and controller synthesis. Both dense-time and discrete-time models are considered. We identify subclasses of rectangular hybrid automata for which these problems are decidable and give complexity analyses. An investigation of the structural properties of rectangular hybrid automata is undertaken. One method for proving the decidability of verification problems on infinite-state systems is to find finite quotient systems on which analysis can proceed. Three state-space equivalence relations with strong connections to temporal logic are bisimilarity, similarity, and language equivalence. We characterize the quotient spaces of rectangular hybrid automata with respect to these equivalence relations.

title: View Synthesis Using Stereo Vision
abstract: This thesis investigates the use of stereo vision for the application of view synthesis. View synthesis --- the problem of creating images of a scene as it would appear from novel viewpoints --- has traditionally been approached using methods from computer graphics. These methods, however, suffer from low rendering speed, limited achievable realism, and, most severely, their dependence on a global scene model, which typically needs to be constructed manually. In this thesis, we present a new approach to view synthesis that avoids the above problems by synthesizing new views from existing images of a scene. Using an image-based representation of scene geometry computed by stereo vision methods, a global model can be avoided, and realistic new views can be synthesized quickly using image warping. The new application of stereo for view synthesis makes it necessary to re-evaluate the requirements on stereo algorithms. We compare view synthesis to several traditional applications of stereo, and conclude that stereo vision is better suited for view

synthesis than for applications requiring explicit 3D reconstruction. We also discuss ways of dealing with partially occluded regions of unknown depth and with completely occluded regions of unknown texture, and present experiments demonstrating that it is possible to efficiently synthesize realistic new views even from inaccurate and incomplete depth information. This thesis also contributes several novel stereo algorithms that are motivated by the specific requirements imposed by view synthesis. We introduce a new evidence measure based on intensity gradients for establishing correspondences between images. This measure combines the notions of similarity and confidence, and allows stable matching and easy assigning of canonical depth interpretations in image regions of insufficient information. We also present new diffusion-based stereo algorithms that are motivated by the need to correctly recover object boundaries. In particular, we develop a novel Bayesian estimation technique that significantly outperforms area-based algorithms using fixed-sized windows. We provide experimental results for all algorithms on both synthetic and real images.

title: Probabilistic Broadcast
abstract: We present a class of scalable and probabilisticly reliable communication protocols. The protocols are based on a probabilistic system model and thus their properties tend to be probabilistic in nature. The protocols are scalable in two senses. First, the message costs and latencies of the protocols grow slowly with the system size. Second, the reliability of the protocols, expressed in terms of the probability of a failed run of a protocol, approaches 0 exponentially fast as the number of processes is increased. This scalable reliability is achieved through a form of gossip protocol which is strongly self-stabilizing in a sense similar, although not identical to, the notion of self stabilizing systems proposed by Dijkstra.

title: Solving Problems in the Presence of Process Crashes and Lossy Links
abstract: We study the effect of link failures on the solvability of problems in asynchronous systems that are subject to process crashes: given a problem that can be solved in a system with process crashes and reliable links, is the problem solvable even if links are lossy? We answer this question for two types of lossy links, and show that the answer depends on the maximum number of processes that may crash and the nature of the problem to be solved. In particular, we prove that the answer is positive if fewer than half of the processes may crash or if the problem specification does not refer to the state of processes that crash. However, in general, the answer is negative even if each link can loose only a finite number of messages.

title: A Dynamic Light-Weight Group Service
abstract: The virtual synchrony model for group communication has proven to be a powerful paradigm for building distributed applications. Implementations of virtual synchrony usually require the use of failure

detectors and failure recovery protocols. In applications that require the use of a large number of groups, significant performance gains can be attained if these groups share the resources required to provide virtual synchrony. A service that maps user groups onto instances of a virtually synchronous implementation is called a Light-Weight Group Service. This paper proposes a new design for the Light-Weight Group protocols that enables the usage of this service in a transparent and dynamic manner. As a test case, the new design was implemented in the Horus system, although the underlying principles can be applied to other architectures as well. The paper also presents performance results from this implementation.

title: Dynamic Light-Weight Groups
abstract: The virtual synchrony model for group communication has proven to be a powerful paradigm for building distributed applications. In applications that require the use of a large number of groups, significant performance gains can be attained if these groups share the resources required to provide virtual synchrony. A service that maps user groups onto instances of a virtually synchronous implementation is called a Light-Weight Group Service. This paper discusses the usage of Light-Weight Group protocols in dynamic environments, where mappings cannot be defined a priori and may change over time. We show that it is possible to establish mappings that promote sharing and, at the same time, minimize interference. These mappings can be established in an automated manner, using heuristics applied locally at each node. Experiments using an implementation in the Horus system show that significant performance improvements can be achieved with this approach.

title: Optimizing Layered Communication Protocols
abstract: Layering of protocols offers several well-known advantages, but typically leads to performance inefficiencies. We present a model for layering, and point out where the performance problems occur in stacks of layers using this model. We then investigate the common execution paths in these stacks and how to identify them. These paths are optimized using three techniques: optimizing the computation, compressing protocol headers, and delaying processing. All of the optimizations can be automated in a compiler with the help of minor annotations by the protocol designer. We describe the performance that we obtain after implementing the optimizations by hand on a full-scale system.

title: Automated Analysis of Fault-Tolerance in Distributed Systems
abstract: This paper describes a method for automated analysis of fault-tolerance properties of distributed systems. The framework is based on ideas from stream-processing semantics for networks of processes and abstract interpretation of programs. The stream-processing model provides modularity and a clean algorithmic basis for the analysis. For efficiency, all aspects of a system's behavior can be approximated in the analysis, including: values (the data transmitted in messages), multiplicities (the number of times each value is sent), and orderings (the order in which values are sent). The approximation mechanisms are based

on abstract interpretation, symbolic computation, and partial orders. Approximations are essential to support abstraction from aspects of a system's behavior that do not directly impact its fault-tolerance. Another feature of our approach is that perturbations due to failures can be represented explicitly. This allows fault-tolerance requirements to be expressed as bounds on the acceptable perturbations to a system's behavior as a consequence of certain failures. This facilitates separation of fault-tolerance from other correctness requirements and sometimes enables more efficient analysis. The analysis has been implemented in a prototype tool.

title: Condition Numbers of Random Triangular Matrices
abstract: \begin{abstract} Let L_n be a lower triangular matrix of dimension n each of whose nonzero entries is an independent $N(0,1)$ variable, \ie, a random normal variable of mean 0 and variance 1. It is shown that $\kn$, the 2-norm condition number of L_n, satisfies \begin{equation*} \sqrt[n]{\kn} \rightarrow 2 \:\:\: \text{\it almost surely} \end{equation*} as $n\rightarrow\infty$. This exponential growth of $\kn$ with n is in striking contrast to the linear growth of the condition numbers of random {\it dense} matrices with n that is already known. This phenomenon is not due to small entries on the diagonal (\ ie, small eigenvalues) of L_n. Indeed, it is shown that a lower triangular matrix of dimension n whose diagonal entries are fixed at 1 with the subdiagonal entries taken as independent $N(0,1)$ variables is also exponentially ill-conditioned with the 2-norm condition number $\kn$ of such a matrix satisfying \ begin{equation*} \sqrt[n]{\kn}\rightarrow 1.305683410\ldots \:\:\:\text{\it almost surely} \end{equation*} as $n\rightarrow\infty$. A similar pair of results about complex random triangular matrices is established. The results for real triangular matrices are generalized to triangular matrices with entries from any symmetric, strictly stable distribution. \end{abstract}

title: Load Balancing Schemes for High-Throughput Distributed Fault-TolerantServers
abstract: Clusters of workstations, connected by a fast network, are emerging as a viable architecture for building high-throughput fault-tolerant servers. This type of architecture is more scaleable and more cost-effective than a tightly coupled multiprocessor and may achieve as good a throughput. Two of the most important issues that a designer of such clustered servers must consider in order for the system to meet its fault-tolerance and throughput goals are the load balancing scheme and the fault-tolerance scheme that the system will use. This paper explores several combinations of such fault tolerance and load-balancing schemes, and compare their impact on the maximum throughout achievable by the system, and on its survivability. In particular, we show that a fault-tolerance scheme may have an effect on the throughput of the system, while a load-balancing scheme may affect the ability of the system to override failures. We study the scaleability of the different schemes under different loads and failure conditions. The validation of our schemes is done using data taken from emulations of an intelligent networking coprocessor of a telephone switch, which follows, for example, the SS7 signaling protocol.

title: The Case for Enhanced Abstract Data Types
abstract: Support for complex data in object-relational database systems is based on abstract data types (ADTs). We argue that the current ADT approach inhibits the performance of queries that involve expensive operations on data types. Instead, we propose the Enhanced Abstract Data Type (E-ADT) paradigm, which treats operations on data types as declarative expressions that can be optimized. In this paper, we describe the E-ADT paradigm and PREDATOR, an object-relational database system based on E-ADTs. An E-ADT is an abstract data type enhanced with query optimization. Not only does an E-ADT provide operations (or methods) that can be used in SQL queries, it also supports internal interfaces that can be invoked to optimize these operations. This added functionality is provided without compromising the modularity of data types and the extensibility of the type system. Building such a database system requires fundamental changes in the architecture of the query processing engine; we present the system-level interfaces of PREDATOR that support E-ADTs, and describe the internal design details. Initial performance results from supporting image, time-series, and audio data as E-ADTs demonstrate an order of magnitude in performance improvements over the current ADT approach. Further, we describe how the E-ADT paradigm enables future research that can improve several aspects of object-relational query optimization. Consequently, we make the case that next-generation object-relational database systems should be based on E-ADT technology.

title: Building a Virtually Fault-Tolerant System
abstract: All schemes for implementing fault-tolerance involve some form of replication. Replicas are assumed to fail independently, and each replica performs the same computation. Replicas may execute in parallel or, in the case of primary-backup protocols, in response to failures. Replication only works, however, if replicas are coordinated. Each replica must receive the same inputs in the same order, and each must be deterministic in its response to these inputs. The key engineering issue that the designer of a fault-tolerant computing system must address is deciding where in the system to implement replica coordination. Some of the alternatives include implementing replica coordination in the processor or network hardware, in the operating system, or in the applications software. A new solution is to implement replica coordination by augmenting the hypervisor of a virtual-machine manager and coordinating a primary virtual machine with its backup. This hypervisor-based fault-tolerance is transparent to the operating system and the applications programs executing above the hypervisor. In addition, this selection allows a single hypervisor design to be used for all processors in an architectural family. In this dissertation, we describe the protocols to implement hypervisor-based fault-tolerance. To assess the practicality of the approach, we constructed a prototype system for HP's PA-RISC architecture. The prototype hypervisor supports a single HP-UX virtual machine and implements the replica-coordination protocols. The prototype hypervisor has been instrumented to measure the overhead of all hypervisor-based activity. We have measured the performance of CPU-intensive workloads and disk I/O intensive workloads in this architecture and have built models allowing us to predict the performance for some alternative architectures.

title: The Maestro Group Manager: A Structuring Tool For Applications WithMultiple Quality of Service Requirements
abstract: {\em Maestro} is a tool for managing sets of protocol stacks that satisfy varied quality of service or

security requirements. Intended primarily for multimedia groupware settings, it permits a single application to efficiently operate over multiple side-by-side protocol stacks, each specialized to a different communication stream. Maestro can also be used to manage other sorts of external protocol stacks, for example to orchestrate connection setups that require coordinated actions at all endpoints in a multicast group. Our tools are fault-tolerant and secure; they can safely distribute session keys or handle delicate synchronization tasks that would otherwise complicate the managed stacks and potentially interfere with their quality-of-service objectives. Moreover, Maestro can automatically track subgroup membership on the basis of ``properties'', facilitating its use by developers who prefer not to work directly with multicast communication interfaces.

title: Incorporating Memory Management into User-Level Network Interfaces
abstract: User-level network interfaces allow applications direct access to the network without operating system intervention on every send and receive. Messages are transferred directly to and from user-space by the network interface while observing the traditional protection boundaries between processes. Current user-level network interfaces limit this message transfer to a per-process region of permanently-pinned physical memory to allow safe DMA. This approach is inflexible in that it requires data to be copied into and out of this memory region, and does not scale to a large number of processes. This paper presents an extension to the U-Net user-level network architecture (U-Net/MM) allowing messages to be transferred directly to and from any part of an application's address space. This is achieved by integrating a translation look-aside buffer into the network interface and coordinating its operation with the operating system's virtual memory subsystem. This mechanism allows network buffer pages to be pinned and unpinned dynamically. Two implementations of U-Net/MM are described, demonstrating that existing commodity hardware and commercial operating systems can efficiently support the architecture.

title: Word Sense Disambiguation Using Numerical Constraint Satisfaction
abstract: In this paper we present a description and evaluation of a word sense disambiguation mechanism that is an extension of the work by Ide and Veronis. The mechanism's underlying approach is a numerical constraint satisfaction algorithm applied to the network built using an on-line dictionary. In this work we aim to duplicate the original results and extend the method to large-scale applications. To determine the scalability of the approach, we evaluate the mechanism on 20 ambiguous words taken in their contexts of different size from the Brown corpus. We offer a discussion of encountered difficulties and describe several possible directions that can be investigated to improve the mechanism's performance and scalability.

title: Specification, Composition, and Automated Verification of LayeredCommunication Protocols
abstract: Horus is a general-purpose layered message-passing system for distributed programming. A programmer of a distributed application can select protocol layers from among those provided by Horus and arrange these in a stack, thereby creating a custom-built message-passing protocol with strong (or not so strong) properties underneath the application. For the full value of Horus's modularity to be exploited, an application programmer must be able to choose just the layers and stacking order that will provide the desired properties. A programmer who is limited to only a few ``tried-and-true'' alternatives may end up paying a performance cost (such as excessive synchronization messages) for unnecessary properties, simply because he or she cannot confidently build a less costly stack underneath a given application. This dissertation describes a formal method that supports the engineering of new Horus protocol stacks by precisely specifying and mechanically verifying communication properties of these stacks. Various communication properties can be described in English, but are also described succinctly in a mathematical model (the Temporal Logic of Actions) that supports sound reasoning about whether the properties are satisfied by an implementation. Each protocol layer guarantees various properties at its interfaces, depending on what assumed properties its neighbors provide to it. Relatively straightforward formal reasoning can then show that certain properties will be provided to the applications at the top of the stack. This method of reasoning about protocol stacks can efficiently be automated so that it can be used by practitioners. A prototype of the verifier has been implemented in Java and published on the World Wide Web.

title: On the Complexity of Reasoning in Kleene Algebra
abstract: We study the complexity of reasoning in Kleene algebra and *-continuous Kleene algebra in the presence of extra equational assumptions E; that is, the complexity of deciding the validity of universal Horn formulas $E\imp s=t$, where E is a finite set of equations. We obtain various levels of complexity based on the form of the assumptions E. Our main results are: for *-continuous Kleene algebra, \begin{itemize} \item if E contains only commutativity assumptions $pq=qp$, the problem is Π_1^0-complete; \item if E contains only monoid equations, the problem is Π_2^0-complete; \item for arbitrary equations E, the problem is Π_1^1-complete. \end{itemize} The last problem is the universal Horn theory of the *-continuous Kleene algebras. This resolves an open question of Kozen (1994).

title: Term Weighting Revisited
abstract: Term weighting is an essential part of the modern information retrieval systems. Out of the three main components of a term weighting strategy --- term frequency, inverse document frequency, and document length normalization --- the term frequency factor has been investigated recently by researchers. In this work, we study the inverse document frequency, and document length normalization components of term weights. We observe that a document length normalization scheme that retrieves documents of all lengths with similar chances as their likelihood of relevance will outperform another scheme which retrieves documents with chances very different from their likelihood of relevance. We present {\em pivoted normalization\/}, a technique that can be used to modify normalization functions to reduce the gap between the relevance and the retrieval probabilities. We present two new normalization functions --- {\em pivoted unique normalization\/} and {\em pivoted byte size normalization}, both of which yield significant improvements over the previous state of the art normalization functions. When optical character recognition is used to create large information bases, term weighting schemes can be highly sensitive to the errors in the input text, introduced by the OCR process. This work examines the effects of the well known {\em cosine normalization\/} method in the presence of OCR errors, and proposes a new, more robust, normalization method. Experiments show that the new scheme is less sensitive to OCR errors and facilitates the use of more diverse basic weighting schemes. This study also explains why the use of cosine normalization in presence of the inverse document frequency factor is not advisable in large document collections. When a user types a natural language query for an IR system, certain keywords in the query are more pertinent to the user's information need than others. Most modern IR systems incorporate these distinctions by using an inverse document frequency ({\em idf\/}) factor in term weighting. Preliminary experiments show that the usefulness of an {\em idf\/} type function is high at low ranks. We observe that the main reason for this effect is the widened gap between the weights of the rare terms and the non-rare query terms. The standard {\em idf\/} function works very well across query sets. Experiments show that there is room for improvement in the {\em idf\/} function. Further studies are needed to discover a better replacement for the standard {\em idf\/} function.

title: A Method and Tool for Analyzing Fault-Tolerance in Systems
abstract: As computers are integrated into systems that have stringent fault-tolerance requirements, there is

a growing need for techniques to establish that these systems actually satisfy those requirements. Informal arguments do not supply the desired level of assurance for critical systems. This dissertation presents a rigorous, automated approach to analyzing distributed systems, with a focus on checking fault-tolerance requirements, and describes a prototype implementation of the analysis. The analysis is a novel hybrid of ideas from stream-processing semantics of networks of processes, abstract interpretation of programs, and symbolic computation. The underlying principles of the analysis method are general, but specialized techniques---such as the use of perturbations to represent changes to normal behavior caused by failures---are developed to deal efficiently with the types of systems and requirements that arise in establishing fault-tolerance. The method is illustrated with three examples: the Oral Messages algorithm for Byzantine Agreement, due to Lamport, Shostak and Pease, a standard protocol for FIFO reliable broadcast, and a (subtly) flawed protocol for fault-tolerant moving agents.

title: Nagging: A General, Fault-Tolerant Approach to Parallel Search Pruning
abstract: For some interesting problems, all known algorithms rely, to some degree, on exhaustive search. Since combinatorial search cannot scale to large problem instances, no general-case solutions to these problems are available. However, because solutions to many of these problems have practical value, various software techniques have been developed to avoid or reduce search in a number of useful, special cases. Unfortunately, different software techniques exhibit varying performance advantages from one problem instance to the next; given a particular problem instance, it is not always clear which approach would be most effective. This paper introduces a parallel search-pruning technique called nagging which is means of coordinating the activity of a number of different search procedures. Under this technique, search-based problem solvers compete in parallel to solve parts of a particular problem instance. Each problem solver contributes to advancing the search wherever it is the most effective. Nagging's intrinsic fault tolerance and scalability make it particularly suitable for commonly available, low-bandwidth, high-latency distributed computing environments. It is sufficiently general to be effective in a number of domains. A prototype implementation has been developed for first-order theorem proving, a domain both responsive to a very simple nagging model and amenable to many refinements of this model. Nagging is evaluated by testing this implementation on a suite of well-known theorem proving problems.

title: Evaluating the Performance Limitations of MPMD Communication
abstract: The MPMD approach for parallel computing is attractive for programmers who seek fast development cycles, high code re-use, and modular programming, or whose applications exhibit irregular computation loads and communication patterns. Remote method invocation is widely adopted as the communication abstraction for crossing address space boundaries. However, the communication overheads of existing RMI-based systems are usually an order of magnitude higher than those found in highly tuned SPMD systems. This problem has thus far limited the appeal of high-level programming languages based on MPMD models in the parallel computing community. This paper investigates the fundamental limitations of MPMD communication using a case study of two parallel programming languages, Compositional C++ (CC++) and Split-C, that provide support for a global name space. To establish a common comparison basis, a new implementation of CC++ was developed to use Active Messages and a native threads package. A series of micro-benchmarks

compares the communication performance of this new CC++ implementation with Split-C on an IBM SP multi-computer. The impact of these costs on three applications is also evaluated and suggests that MPMD communication can be used effectively in many high-performance parallel applications.

title: Heartbeat: A Timeout-Free Failure Detector for Quiescent ReliableCommunication
abstract: We study the problem of achieving reliable communication with quiescent algorithms (i.e., algorithms that eventually stop sending messages) in asynchronous systems with process crashes and lossy links. We first show that it is impossible to solve this problem without failure detectors. We then show how to solve it using a new failure detector, called heartbeat. In contrast to previous failure detectors that have been used to circumvent impossibility results, the heartbeat failure detector is implementable, and its implementation does not use timeouts. These results have wide applicability: they can be used to transform many existing algorithms that tolerate only process crashes into quiescent algorithms that tolerate both process crashes and message losses. This can be applied to consensus, atomic broadcast, k-set agreement, atomic commitment, etc. The heartbeat failure detector is novel: it is implementable without timeouts and it does not output lists of suspects as typical failure detectors do. If we restrict failure detectors to output only lists of suspects, quiescent reliable communication requires less than or greater than P [ACT97a], which is not implementable. Combined with the results of this paper, this shows that traditional failure detectors that output only lists of suspects have fundamental limitations.

title: Quiescent Reliable Communication and Quiescent Consensus inPartitionable Networks
abstract: We consider partitionable networks with process crashes and lossy links, and focus on the problems of reliable communication and consensus for such networks. For both problems we seek algorithms that are quiescent, i.e., algorithms that eventually stop sending messages. We first tackle the problem of reliable communication for partitionable networks by extending the results of [ACT97a]. In particular, we generalize the specification of the heartbeat failure detector HB, show how to implement it, and show how to use it to achieve quiescent reliable communication. We then turn our attention to the problem of consensus for partitionable networks. We first show that, even though this problem can be solved using a natural extension of less than or greater than S, such solutions are not quiescent --- in other words, less than or greater than S alone is not sufficient to achieve quiescent consensus in partitionable networks. We then solve this problem using less than or greater than S and the quiescent reliable communication primitives that we developed in the first part of the paper. Our model of failure detectors for partitionable networks, a natural extension of the model in [CT96], is also a contribution of this paper.

title: A Theory of Interleavers
abstract: An interleaver is a hardware device commonly used in conjunction with error correcting codes to counteract the effect of burst errors. Interleavers are in widespread use and much is known about them from an engineering standpoint. In this paper we propose a mathematical model that provides a rigorous foundation for the theoretical study of interleavers. The model captures precisely such notions as block and convolutional interleavers, spread, periodicity, causality, latency, and memory usage. Using this model, we derive several optimality results on the latency and memory usage of interleavers. We describe a family of block interleavers and show that they are optimal with respect to latency among all block interleavers with a given spread. We also give tight upper and lower bounds on the memory requirements of interleavers.

title: A Relational Approach to the Automatic Generation of Sequential SparseMatrix Codes
abstract: This thesis presents techniques for automatically generating sparse codes from dense matrix algorithms through a process called \emph{sparse compilation}. We will start by recognizing that sparse computations are ubiquitous to scientific computation, that these codes are difficult to write by hand, and that they are difficult for conventional compilers to optimize. We will present the sparse compiler as an alternative to writing these codes by hand or using sparse libraries. We will show how many aspects of sparse compilation can be modeled in terms of relational database concepts, These include the following: queries to express sparse computations, relations to model sparse matrices, the join operation to model simultaneous efficient access of sparse matrices. Using this model, the problem of sparse compilation can be seen as an instance of the query optimization problem. We will discuss two basic strategies for sparse compilation based upon this relational approach. One strategy is targeted towards algorithms that can be described using inner join queries, which include matrix-vector multiplication and matrix-matrix multiplication. This approach is the one that we have currently implemented. The other can handle a larger class of dependence-free matrix algorithms. Although it is more general, the latter approach introduced does not generate as efficient code for some problems as the former approach. We will show that these two approaches are grounded in properties of the relational algebra and draw connections with previous work that has been described in the database literature. We also discuss how conventional dense optimizations and fill can be handled within the overall relational framework. We will discuss the Bernoulli Sparse Compiler and use experimental results to show that this system is able to generate sparse implementations from non-trivial dense matrix algorithms that are as efficient as hand-written codes. In addition, this compiler provides a novel mechanism that allows the user to extend its repertoire of sparse matrix storage formats. Thus, the user is not only able to choose the data structures for storing the sparse matrices, but to describe these data structures as well.

title: High-Performance Replicated Distributed Objects in PartitionableEnvironments
abstract: This paper presents an implementation of replicated distributed objects in asynchronous environments prone to node failures and network partitions. This implementation has several appealing properties: It guarantees that progress will be made whenever a majority of replicas can communicate with each other; it allows minority partitions to continue providing service for idempotent requests; it offers the application the choice between optimistic or safe message delivery. Performance measurements have shown that our implementation incurs low latency and achieves high throughput while providing globally consistent replicated state machine semantics. The paper discusses both the protocols and interfaces to support efficient object replication at the application level.

title: Combining Trust Region and Affine Scaling Linearly ConstrainedNonconvex Minimization
abstract: An interior point method is proposed for a general nonlinear (nonconvex) minimization with linear inequality constraints. This method is a combination of the trust region idea for nonlinearity and affine scaling technique for constraints. Using this method, the original objective function is monotonically decreased. In the proposed approach, a Newton step is derived directly from the complementarity conditions. A trust region subproblem is formed which yields an approximate Newton step as its solution asymptotically. The objective function of the trust region subproblem is the quadratic approximation to the original objective function plus an augmented quadratic convex term. Similar to an augmented Lagrangian function, this augmentation adds positive curvature in the range space of the constraint normals. The global convergence is achieved by possibly using trust regions with different shapes. A reflection technique, which accelerates convergence, is described. Explicit sufficient decrease conditions are proposed. Computational results of a two-dimensional trust region implementation are reported for large-scale problems. Preliminary experiments suggest that this method can be effective; a relatively small number of function evaluations are required for some medium and large test problems.

title: A Trust Region and Affine Scaling Interior Point Method for NonconvexMinimization with Linear Inequality Constraints
abstract: A trust region and affine scaling interior point method (TRAM) is proposed for a general nonlinear minimization with linear inequality constraints in [8]. In the proposed approach, a Newton step is derived from the complementarity conditions. Based on this Newton step, a trust region subproblem is formed, and the original objective function is monotonically decreased. Explicit sufficient decrease conditions are proposed for satisfying complementarity, dual feasibility and second order optimality. The objective of this paper is to establish global and local convergence properties of the proposed trust region and affine scaling interior point method. It is shown that the proposed decrease conditions are sufficient for achieving complementarity, dual feasibility and second order optimality respectively. It is also established that a trust region solution is asymptotically in the interior of the proposed trust region subproblem and a damped trust region step can achieve quadratic convergence.

title: Improving the Efficiency of Nuprl Proofs
abstract: In order to use Nuprl system as a programming language with built-in verification one has to improve the efficiency of the programs extracted from the Nuprl proofs. In the current paper we consider proofs from the Nuprl automata library. In some of these proofs (pigeon-hole principle, decidability of the state reachability, decidability of the equivalence relation on words induced by the automata language) sources of exponential-time complexity have been detected and replaced by new complexity cautious proofs. The new proofs now lead to polynomial-time algorithms extracted by the same Nuprl extractor, thus eliminating all known unnecessary exponentials from the Nuprl automata library. General principles of efficient programming on Nuprl are also discussed. Key Words and Phrases: automata, constructivity, Myhill-Nerode theorem, Nuprl, program extraction, program verification, state minimization.

title: Mostly-Copying Collection: A Viable Alternative to ConservativeMark-Sweep
abstract: Many high-level language compilers generate C code and then invoke a C compiler to do code generation, register allocation, stack management, and low-level optimization. To date, most of these compilers link the resulting code against a conservative mark-sweep garbage collector in order to reclaim unused memory. We introduce a new collector, MCC, based on mostly-copying collection, and characterize the conditions that favor such a collector over a mark-sweep collector. In particular we demonstrate that mostly-copying collection outperforms conservative mark-sweep under the same conditions that accurate copying collection outperforms accurate mark-sweep: Specifically, MCC meets or exceeds the performance of a mature mark-sweep collector when allocation rates are high, and physical memory is large relative to the live data.

title: Concurrent Refinement in Nuprl
abstract: This dissertation reports on the design, implementation, and analysis of the first parallel interactive theorem prover, called the MP refiner. The MP refiner is a shared memory multi-processor implementation of the inference engine of Nuprl. The inference engine of Nuprl is called the refiner. The MP refiner is implemented in the functional programming language Standard ML and is compatible with the refiner of Nuprl 4.1. Parallelism is provided in the MP refiner using an extension to the runtime system of the SML/NJ compiler for Standard ML. The MP refiner provides AND-parallelism and OR-parallelism expressed in terms of concurrent tactics. Concurrent tactics are created using the new tacticals PTHEN and PORELSLEL. The process of evaluating concurrent tactics is called concurrent refinement. The MP refiner is a collection of threads operating as sequential refiners running on separate processors. Concurrent tactics exploit parallelism by spawning tactics to be evaluated by other refiner threads simultaneously. Tests conducted with the MP refiner running on a four processor Sparc shared--memory multi-processor reveal that concurrent refinement can significantly decrease the elapsed time of constructing proofs interactively. The concurrent tactics constructed with course-grain tactics gave speedups slightly less than two. On the other hand, the concurrent tactics using fine-grain tactics gave speedups close to three. The granularity of a tactic depends on the amount of primitive inferences it invokes. The poor speedups of concurrent tactics constructed with course-grain tactics resulted from bus contention between the multiple processors caused by the memory

management of SML/NJ. The design of the MP refiner is based on a rigorous mathematical description of the refiner. The mathematical description includes a model of concurrent refinement. In addition, this disseration presents the first complete rigorous presentation of the Nuprl second order substitution algorithm and the first thorough description of the various components that make up the refiner.

title: Hierarchical Message Stability Tracking Protocols
abstract: Protocols which track message stability are an important part of reliable multicast protocols in fault-tolerant distributed systems. To reliably deliver multicast messages in a process group, each process maintains copies of all messages it sends and receives. If a member fails to receive a message, any process which has the message in its buffer can retransmit it. In order to prevent these buffers from growing out of bound, stability tracking protocols must be used. That is, whenever a process learns that a message has been received by everyone, it declares this message {\it stable} and releases it from the buffer. We investigate several message stability tracking protocols commonly used in a number of popular reliable multicast protocols with a focus on their performance in large scale settings with thousands of participants. To improve the scalability of these protocols significantly, we derive a set of new protocols using a spanning tree structure which scale to at least tens of thousands of participants.

title: PROGRAMMABLE FORCE FIELDS FOR DISTRIBUTED MANIPULATION, AND THEIRIMPLEMENTATION USING MICRO-FABRICATED ACTUATOR ARRAYS
abstract: Programmable force vector fields can be used to control a variety of flexible planar parts feeders such as massively-parallel micro actuator arrays or transversely vibrating (macroscopic) plates. These new automation designs promise great flexibility, speed, and dexterity---they may be employed to position, orient, singulate, sort, feed, and assemble parts. A wealth of geometric and algorithmic problems arise in the control and programming of manipulation systems with many independent actuators. The theory of programmable force fields represents the first systematic attack on massively-parallel distributed manipulation based on geometric and physical reasoning. We show how to develop combinatorially precise planning algorithms that synthesize force field strategies for controlling a very large number of distributed actuators in a principled, geometric, task-level fashion. When a part is placed on our devices, the programmed force field induces a force and moment upon it. Over time, the part may come to rest in a dynamic equilibrium state. By chaining together sequences of force fields, the equilibrium states of a part in the field may be cascaded to obtain a desired final state. The resulting strategies require no sensing and enjoy efficient planning algorithms. This thesis introduces new experimental devices that can implement programmable force fields. In particular, we describe the M-Chip (Manipulation Chip), a massively-parallel array of programmable micro-motion pixels. Both the M-Chip, as well as macroscopic devices such as transversely vibrating plates, may be programmed with force fields, and their behavior predicted and controlled using our equilibrium analysis. We demonstrate lower bounds (i.e., impossibility results) on what the devices cannot do, and results on a classification of control strategies yielding design criteria by which well-behaved manipulation strategies may be developed. We define composition operators to build complex strategies from simple ones, and show the resulting fields are also well-behaved. Finally, we consider parts feeders that can only implement a very limited ``vocabulary'' of force fields. We show how to plan and execute parts-posing and orienting strategies for these devices,

but with a significant increase in planning complexity and some sacrifice in completeness guarantees. We discuss the tradeoff between mechanical complexity and planning complexity.

title: Random Fibonacci sequences and the number 1.13198824...
abstract: \begin{abstract} For the familiar Fibonacci sequence --- defined by $f_1 = f_2 = 1$, and $f_n = f_{n-1} + f_{n-2}$ for $n greater than 2$ --- f_n increases exponentially with n at a rate given by the golden ratio $(1+\sqrt{5})/2=1.61803398\ldots$. But for a simple modification with both additions and subtractions --- the {\it random} Fibonacci sequences defined by $t_1=t_2=1$, and for $n greater than 2$, $t_n = \pm t_{n-1} \pm t_{n-2}$, where each $\pm$ sign is independent and either $+$ or $-$ with probability $1/2$ --- it is not even obvious if $\abs{t_n}$ should increase with n. Our main result is that \begin{equation*} \sqrt[n]{\abs{t_n}} \rightarrow 1.13198824\ldots\:\:\: \text{as}\:\:\: n \rightarrow\infty \end{equation*} with probability 1. Finding the number $1.13198824\ldots$ involves the theory of random matrix products, Stern-Brocot division of the real line, a fractal-like measure, a computer calculation, and a rounding error analysis to validate the computer calculation. \end{abstract}

title: From System F to Typed Assembly Language (Extended Version)
abstract: We motivate the design of a statically typed assembly language (TAL) and present a type-preserving translation from System F to TAL. The TAL we present is based on a conventional RISC assembly language, but its static type system provides support for enforcing high-level language abstractions, such as closures, tuples, and objects, as well as user-defined abstract data types. The type system ensures that well-typed programs cannot violate these abstractions. In addition, the typing constructs place almost no restrictions on low-level optimizations such as register allocation, instruction selection, or instruction scheduling. Our translation to TAL is specified as a sequence of type-preserving transformations, including CPS and closure conversion phases; type-correct source programs are mapped to type-correct assembly language. A key contribution is an approach to polymorphic closure conversion that is considerably simpler than previous work. The compiler and typed assembly language provide a fully automatic way to produce proof carrying code, suitable for use in systems where untrusted and potentially malicious code must be checked for safety before execution.

title: Distributed Communication in ML
abstract: We present our experience in implementing a group communication toolkit in Objective Caml, a dialect of the ML family of programming languages. We compare the toolkit both quantitatively and qualitatively to a predecessor toolkit which was implemented in C. Our experience shows that using the high-level abstraction features of ML gives substantial advantages. Some of these features, such as automatic memory management and message marshalling, allowed us to concentrate on those pieces of the implementation which required careful attention in order to achieve good performance. We conclude with a set of suggested changes to both the ML language and the particular implementation we used.

title: Superlinearly Convergent Variable Metric Algorithms for General Nonlinear Programming Problems
abstract: In this paper variable metric algorithms are extended to solve general nonlinear programming problems. In the algorithm we iteratively solve a linearly constrained quadratic program which contains an estimate of the Hessian of the Lagrangian. We suggest the variable metric updates for the estimates of the Hessians and justify our suggestion by showing that, when some well known update such as the Davidon-Fletcher-Powell update are so employed, the algorithm converges locally with a superlinear rate. Our algorithm is in a sense a natural extension of the variable metric algorithm to the constrained optimization and this extension offers us not only a class of effective algorithms in nonlinear programming but also a unified treatment of constrained and unconstrained optimization in the variable metric approach.

title: USING SOFTWARE DESIGN PATTERNS TO BUILD DISTRIBUTED ENVIRONMENTALMONITORING APPLICATIONS
abstract: Tools developers face the challenge of exposing a development methodology to users while concealing details of the underlying system. If that system is complex and subject to evolution, this problem can be particularly difficult. Here, we discuss the use of software design patterns in conjunction with StormCast, a system of tools developed to support environmental and weather monitoring tasks in the Arctic. Now entering its 5th generation, each version of StormCast has expanded the capabilities of the underlying distributed data management tools and computational facilities. This paper reviews StormCast 5.0, presents the design patterns used by developers, and describes several applications in terms of the application of these patterns.

title: GSGC: An Efficient Gossip-Style Garbage Collection Scheme for ScalableReliable Multicast
abstract: To deliver multicast messages reliably in a group, each member maintains copies of all messages it sends and receives in a buffer for potential local retransmission. The storage of these messages is costly and buffers may grow out of bound. Garbage collection is needed to address this issue. Garbage collection occurs once a process learns that a message in its buffer has been received by every process in the group. The message is declared stable and is released from the process's buffer. This paper proposes a gossip-style garbage collection scheme called GSGC for scalable reliable multicast protocols. This scheme achieves fault-tolerance and scalability without relying on the underlying multicast protocols. It collects and disseminates information in the multicast group by making each group member periodically gossip information to a random subset of the group. Extending the global gossip protocol further, this paper also investigates a local gossip scheme that achieves improved scalability and significantly better performance. Simulations conducted in a WAN environment are used to evaluate the performance of both schemes.

title: A Variable Window Approach to Early Vision
abstract: Early vision relies heavily on rectangular windows for tasks such as smoothing and computing correspondence. While rectangular windows are efficient, they yield poor results near object boundaries. We describe an efficient method for choosing an arbitrarily shaped connected window, in a manner which varies at each pixel. Our approach can be applied to many problems, including image restoration and visual correspondence. It runs in linear time, and takes a few seconds on traditional benchmark images. Performance on both synthetic and real imagery with ground truth appears promising.

title: Markov Random Fields with Efficient Approximations
abstract: Markov Random Fields (MRF's) can be used for a wide variety of vision problems. In this paper we address the estimation of first-order MRF's with a particular clique potential that resembles a well. We show that the maximum {\em a posteriori} estimate of such an MRF can be obtained by solving a multiway cut problem on a graph. This allows the application of near linear-time algorithms for computing provably good approximations. We formulate the visual correspondence problem as an MRF in our framework, and show that this yields quite promising results on real data with ground truth.

title: Precision Weighting - An Effective Automatic Indexing Method
abstract: A great many automatic indexing methods have been implemented and evaluated over the last few

years, and automatic procedures comparable in effectiveness to conventional manual ones are now easy to generate. Two drawbacks of the available automatic indexing methods are the absence of reliable linguistic inputs during the indexing process, and the lack of formal, analytical proofs concerning the effectiveness of the proposed methods. The precision weighting procedure described in the present study uses relevance criteria to weight the terms occurring in user queries as a function of the balance between relevant and nonrelevant documents in which these terms occur; this approximates a semantic know-how of term importance. Formal mathematical proofs are given under well-defined conditions of the effectiveness of the method.

title: Implementing Multiple Protection Domains in Java
abstract: Safe language technology can be used for protection within a single address space. This protection is enforced by the language's type system, which ensures that references to objects cannot be forged. A safe language alone, however, lacks many features taken for granted in more traditional operating systems, such as rights revocation, thread protection, resource management, and support for domain termination. This paper describes the J-Kernel, a portable Java-based protection system that addresses these issues. A number of micro-benchmarks are presented to characterize the costs of language-based protection, and an extensible web server based on the J-Kernel demonstrates the use of safe language techniques in a large application.

title: The Ensemble System
abstract: Ensemble is a group communication system that demonstrably achieves a wide range of goals. It is a general-purpose communication system intended for constructing reliable distributed applications; it is a flexible framework for carrying out research in group ware protocols; it is a large-scale, system-style implementation built in a state-of-the-art programming language\rc{lines of ML?}; and it is also a mathematical object designed to be amenable to formal analysis and manipulation. Thus, Ensemble straddles a number of disciplines of computer science ranging from systems architectures to formal methods. The principal advances described in this thesis are the creation of the Ensemble system and the demonstration that it exhibits the properties just mentioned. The thesis begins by presenting the Ensemble architecture, as well as background in group communication. We describe the various components of the architecture, give examples of their

interactions, and compare this architecture with that of other layered communication systems. The Ensemble protocols make heavy use of layered micro-protocols. We describe optimization techniques that greatly reduce the performance overheads introduced by layering and show how the architecture facilitates these optimizations. In addition we show how to formalize these optimizations in type theory and implement them using the Nuprl theorem prover. Ensemble is implemented in a dialect of the ML programming language. We describe how the use of ML impacted the system, and present a wide range of comparisons between Ensemble and a similar system implemented in C.

title: Programming Language Semantics in Foundational Type Theory
abstract: There are compelling benefits to using foundational type theory as a framework for programming language semantics. I give a semantics of an expressive programming calculus in the foundational type theory of Nuprl. Previous type-theoretic semantics have used less expressive type theories, or have sacrificed important programming constructs such as recursion and modules. The primary mechanisms of this semantics for the core calculus are partial types, for typing recursion, set types, for encoding power and

singleton kinds, which are used for subtyping and module programming, and very dependent function types, for encoding signatures. I then extend the semantics to modules using phase-splitting.

title: Addition Requirements for Rational Functions
abstract: A notion of rank or independence for arbitrary sets of rational functions is developed, which bounds from below the number of additions and subtractions required of all straight-line algorithms which compute those functions. This permits a uniform derivation of the best lower bounds known for a number of familiar sets of rational functions. The result is proved without the use of substitution arguments. This not only provides an interesting contrast to standard approaches for arithmetic lower bounds, but also allows the algebraic setting to be somewhat generalized. Keywords: additions, algorithms, analysis of algorithms, arithmetic complexity, computational complexity, dimensionality, lower bounds, matrix multiplication, optimality, polynomials, rational functions.

title: Typed Kleene Algebra
abstract: In previous work we have found it necessary to argue that certain theorems of Kleene algebra hold even when the symbols are interpreted as nonsquare matrices. In this note we define and investigate typed Kleene algebra, a typed version of Kleene algebra in which objects have types s pointing to t. Although nonsquare matrices are the principal motivation, there are many other useful interpretations: traces, binary relations, Kleene algebra with tests. We give a set of typing rules and show that every expression has a unique most general typing (mgt). Then we prove the following metatheorem that incorporates the abovementioned results for nonsquare matrices as special cases. Call an expression 1-free if it contains only the Kleene algebra operators (binary) +, (unary) +, 0, and ., but no occurrence of 1 or *. Then every universal 1-free formula that is a theorem of Kleene algebra is also a theorem of typed Kleene algebra under its most general typing. The metatheorem is false without the restriction to 1-free formulas.

title: A Case for Language-Based Protection
abstract: The use of language mechanisms to enforce protection boundaries around software modules has become increasingly attractive. This paper examines the advantages and disadvantages of language-based protection over more traditional protection mechanisms, such as standard virtual memory protection

hardware, software fault isolation, and capability systems. Arguably, state-of-the-art language-based protection is more flexible and as safe as these other mechanisms. Two major remaining issues are the performance of language-based protection, and the management of resources. Regarding the latter, techniques to build an operating system kernel capable of managing resources and revoking rights are presented.

title: An Efficient Algorithm for Polymer Sequence Design
abstract: Polymer sequence design is a natural inverse problem to protein structure prediction: given a target structure in three dimensions, we wish to design an amino acid sequence that will fold to it. A model of Sun, Brem, Chan, and Dill casts this problem as an optimization on a space of sequences of hydrophobic (H) and polar (P) monomers; the goal is to find a sequence which achieves a dense hydrophobic core with few solvent-exposed hydrophobic residues. Sun et al. developed a heuristic method to search the space of sequences, without a guarantee of optimality or near-optimality; Hart subsequently raised the computational tractability of constructing an optimal sequence in this model as an open question. Here we answer this question by providing an efficient algorithm to construct optimal sequences; the method has a polynomial running time, and performs very efficiently in practice. We illustrate the implementation of our method on structures drawn from the Protein Data Bank, and discuss some possible extensions of the model.

title: Frequency vs. Probability Formats: Framing the Three Doors Problem
abstract: Instead of subscribing to the view that people are unable to perform Bayesian probabilistic inference, recent research suggests that the algorithms people naturally use to perform Bayesian inference are better adapted for information presented in a natural frequency format than in the common probability format. We tested this hypothesis on the notoriously difficult three doors problem, inducing subjects to consider the likelihoods involved in terms of natural frequencies or in terms of probabilities. We then examined their ability to perform the mathematics underlying the problem, a stronger indication of Bayesian inferential performance than merely whether they gave the correct answer to the problem. With a robustness that may surprise people unfamiliar with the effects of information formats, the natural frequency group demonstrated dramatically greater normative mathematical performance than the probability group. This supports the importance of information formats in a more complex context than in previous studies.

title: Dead Code Elimination Through Type Inference
abstract: We introduce a method to detect and eliminate dead code in typed functional programming languages. Our approach relies on a type system with simple subtypes for specifying dead code and a type inference algorithm for it. Through a careful seperation of the type system and the problem-specific assumptions we avoid \emph{ad hoc} rules in the type system. This, combined with the fact that our approach makes the flow information in a program explicit and is based on well-understood concepts makes our approach a good candidate for a general framework for program analysis. Our technique can be used in

optimizing compilers, optimization of programs extracted from theorem provers, optimization of modular systems, and other areas of software engineering.

title: Admissibility of Fixpoint Induction over Partial Types
abstract: Partial types allow the reasoning about partial functions in type theory. The partial functions of main interest are recursively computed functions, which are commonly assigned types using fixpoint induction. However, fixpoint induction is valid only on admissible types. Previous work has shown many types to be admissible, but has not shown any dependent products to be admissible. Disallowing recursion on dependent product types substantially reduces the expressiveness of the logic; for example, it prevents much reasoning about modules, objects and algebras. In this paper I present two new tools, predicate-admissibility and monotonicity, for showing types to be admissible. These tools show a wide class of types to be admissible; in particular, they show many dependent products to be admissible. This alleviates difficulties in applying partial types to theorem proving in practice. I also present a general least upper bound theorem for fixed points with regard to a computational approximation relation, and show an elegant application of the theorem to compactness.

title: Simple, Efficient Object Encoding using Intersection Types
abstract: I present a type-theoretic encoding of objects that interprets method dispatch by self-application (i.e., method functions are applied to the objects containing them) but still validates the expected subtyping relationships. The naive typing of self-application fails to validate the expected subtyping relationships because it is too permissive and allows application to similarly typed objects that are not self. This new encoding solves this problem by constraining methods to be applied only to self using existential and intersection types. Using this typing, I give a full account of objects including self types and method update. I also present another application of this object encoding to fully abstract, closure-passing closure conversion. The typing constructs used in this encoding appear to be quite rich, but they may be axiomatized in a novel, restricted fashion that is metatheoretically simple.

title: Failure Detection and Consensus in the Crash-Recovery Model
abstract: We study the problems of failure detection and consensus in asynchronous systems in which processes may crash and recover, and links may lose messages. We first propose new failure detectors that are particularly suitable to the crash-recovery model. We next determine under what conditions stable storage is necessary to solve consensus in this model. Using the new failure detectors, we give two consensus algorithms that match these conditions: one requires stable storage and the other does not. Both algorithms tolerate link failures and are particularly efficient in the runs that are most likely in practice --- those with no failures or failure detector mistakes. In such runs, consensus is achieved within 3d time and with 4n messages, where d is the maximum message delay and n is the number of processes in the system.

title: Wavelength Conversion in Optical Networks
abstract: In many models of optical routing, we are given a set of communication paths in a network, and we must assign a wavelength to each path so that paths sharing an edge receive different wavelengths. The goal is to assign as few wavelengths as possible, in order to make as efficient use as possible of the optical bandwidth. Wilfong and Winkler considered the problem of placing wavelength converters in such a network: if a node of the network contains a converter, any path that passes through this node may change its wavelength. Having converters at some of the nodes can reduce the number of wavelengths required for routing, down to the following natural {\em congestion bound}: even with converters, we will always need at least as many wavelengths as the maximum number of paths sharing a single edge. Thus Winkler and Wilfong defined a set S of nodes in a network to be {\em sufficient} if, placing converters at the nodes in S, every set of paths can be routed with a number of wavelengths equal to its congestion bound. They showed that finding a sufficient set of minimum size is NP-complete. In this paper, we provide a polynomial-time algorithm to find a sufficient set for an arbitrary directed network whose size is within a factor of 2 of minimum. For the special case of planar graphs with bi-directional edges, we obtain a polynomial-time approximation scheme. Our techniques establish a connection between the problem of finding a minimum sufficient set and an interesting simultaneous generalization of the Vertex Cover and Feedback Vertex Set problems in undirected graphs.

title: JRes: A Resource Accounting Interface for Java
abstract: In order to better support the Internet the computing model on server systems is undergoing several important changes. First, recent research ideas concerning dynamic operating system extensibility are finding their way into the commercial domain, resulting in designs of extensible databases and Web servers. Second, both ordinary users and service providers must deal with untrusted downloadable executable code of unknown origin and intentions. Across the board, Java has emerged as the language of choice for Internet-oriented software. We argue that, in order to realize its full potential in applications dealing with untrusted code, Java needs a flexible resource accounting interface. The design and prototype implementation of such an interface JRes - is presented in this paper. The interface allows to account for heap memory, CPU time, and network resources consumed by individual threads or collections of threads. JRes allows limits to be set on resources available to threads and it can invoke callbacks when these limits are exceeded. The JRes

prototype described in this paper is implemented on top of standard Java virtual machines and requires only a small amount of native code.

title: Designing a Calculational Logic Theorem Prover: Insight into SearchProcedure via Eye Movements
abstract: We are designing and implementing an automated theorem prover that will in part attempt to simulate human performance on calculational logic theorem proving. To support this project, we recorded and analyzed people's eye movements while they constructed calculational proofs. Our findings confirm some expected behaviors (based on strategies and principles taught to students) that may previously have seemed untestable, such as the influence of the form of the current proof step and of syntax in general on the microcognition of the problem solver. The experiment also uncovered other interesting patterns, such as the seemingly inefficient but widely occurring tendency to attend to premises that are not used in the proof under consideration. Overall, we gained insights into microcognition that could not have been gained merely by studying written proofs. We expect these insights to directly impact the theorem prover under development, but they may also find a wider audience, appealing to educators and logicians who are familiar with calculational methods and student performance on calculational proofs. Our findings also support the notion that analyses of eye movements can improve our understanding of the way people perform some theorem proving tasks.

title: STRUCTURED AUTOMATIC DIFFERENTIATION
abstract: Differentiation is one of the fundamental problems in numerical mathemetics. The solution of many optimization problems and other applications require knowledge of the gradient, the Jacobian matrix, or the Hessian matrix of a given function. Many large scale optimization applications (e.g., inverse problems) are very complex in nature. It becomes impractical to consider the function evaluation of such problems as a ``black-box'' function, since the computation is structured in some manner, going through a set of defined structured steps, i.e., problem structure. It pays to expose the problem structure in the computation to be able to compute the derivatives efficiently thus making the solution procedure practical. Automatic differentiation (AD) can compute fast and accurate derivatives of any degree computationally via propagating Taylor series coefficients using the chain rule. AD doesn't incur any truncation error and to compute the derivatives efficiently thus making the problem solution practical. would yield exact results if the calculations were done in real arithmetic; in other words the derivatives obtained are accurate to machine precision. This thesis is concerned with the efficient application of AD to large (and complex) optimization problems. The major theme is the structure exploitation of the user problem. We present methodologies which allow AD to exploit problem structure. An important idea is the exploitation of sparsity in the Jacobian matrices: We present a scheme which combines the forward and reverse modes of AD. Problem structure can be viewed in many different ways; one way is to look at the granularity of the operations involved. For example, differentiation carried out at the matrix-vector operations can lead to great savings in the time as well as space requirements. Figuring out the {\em kind} of computation is another way to view structure, e.g., partially separable or composite functions whose structur e can be exploited to get performance gains. In this thesis we develop a general structure framework which can be viewed hierarchically and allows for structure exploitation at various levels. For example, for time integration schemes employing stencils it is possible to exploit structure

at both the stencil level and the timestep level. We also present some advanced structure exploitation ideas, e.g., parallelism in structured computations and using structure in implicit computations. The use of AD as a derivative computing engine naturally automates all the methodologies presented in this work -- we present ways to make the design of numerical optimization software very transparent, and the presentation of problems by the user as easy as possible.

title: Scalable Message Stability Detection Protocols
abstract: In group communication, in order to deliver multicast messages reliably in a group, it is common practice for each member to maintain copies of all messages it sends and receives in a buffer for potential local retransmission. The storage of these messages is costly and buffers may grow out of bound. A form of garbage collection is needed to address this issue. Garbage collection occurs once a process learns that a message in its buffer has been received by every process in the group. The message is declared {\it stable} and is released from the buffer. An important part of garbage collection is message stability detection. This dissertation presents the result of an investigation into message stability detection protocols. A number of message stability detection protocols used in popular reliable multicast protocols are studied with a focus on their performance in large scale settings. This dissertation proposes a new gossip-style protocol with improved scalability and fault tolerance. This dissertation also shows that by adding a hierarchical structure to the set of basic protocols, their performance can be significantly improved when the number of participants is large.

title: Parallel Computing as a Commodity
abstract: Massively parallel computers have become undisputed champions in the supercomputing arena. The global computer industry, however, is increasingly dominated by consumer machines. In this thesis, we

argue that everyday computers must become highly parallel machines in order to sustain the performance gains we have come to expect. For parallel computation to become a commodity, there must be an architecture which can be scaled as easily as memory arrays are now. We also need to establish that parallelism can benefit everyday applications and that operating systems for such machines can provide as comfortable and robust an environment as we have on sequential machines. We introduce an architecture based on cellular automata---meshes of simple, locally-connected processors in either 2 or 3 dimensions. We argue that this architecture is easily scalable, and from a theoretical viewpoint it is essentially as efficient as any other scalable architecture. We show two instances of this architecture, a simple one implemented in silicon and a more complex one implemented through a simulator. To show the viability of this architecture for everyday tasks, we have developed fast parallel algorithms for RSA encryption (using residue number systems and a new method for converting one RNS to another) and for document formatting (using a space-filling curve for data layout to achieve optimal $O(\droot{n})$ running time on a d-dimensional mesh). We also describe the design of an operating system for a cellular array based on the notion of the OS as the periphery, rather than the kernel, and show several advantages in security and performance this confers. Finally, we investigate the 3-dimensional dynamic allocation problem faced by such a system. This problem is NP-hard even in its static form, but we describe a simple best-fit allocator that works well in practice.

title: Formalizations Of Substitution Of Equals For Equals
abstract: Inference rule "substitution of equals for equals" has been formalized in terms of simple substitution (which performs a replacement even though a free occurrence of a variable is captured), contextual substitution (which prevents such capture), and function application. We show that in connection with pure first-order predicate calculus, the function-application and no-capture versions of the inference rule are the same and are weaker than the capture version. We discuss the deductive apparatus needed for the no-capture version to be as powerful as the capture version.

title: A Gossip-Style Failure Detection Service
abstract: Failure Detection is valuable for system management, replication, load balancing, and other distributed services. To date, Failure Detection Services scale badly in the number of members that are being monitored. This paper describes a new protocol based on gossiping that does scale well and provides timely detection. We analyze the protocol, and then extend it to discover and leverage the underlying network topology for much improved resource utilization. We then combine it with another protocol, based on broadcast, that is used to handle partition failures.

title: On Quiescent Reliable Communication
abstract: We study the problem of achieving reliable communication with quiescent algorithms (i.e., algorithms that eventually stop sending messages) in asynchronous systems with process crashes and lossy links. We first show that it is impossible to solve this problem without failure detectors. We then show that, among failure detectors that output lists of suspects, the weakest one that can be used to solve this problem is less than or greater than P, a failure detector that cannot be implemented. To overcome this difficulty, we introduce an implementable failure detector called Heartbeat and show that it can be used to achieve quiescent reliable

communication. Heartbeat is novel: in contrast to typical failure detectors, it does not output lists of suspects and it is implementable without timeouts. With Heartbeat, many existing algorithms that tolerate only process crashes can be transformed into quiescent algorithms that tolerate both process crashes and message losses. This can be applied to consensus, atomic broadcast, k-set agreement, atomic commitment, etc.

title: Relational Query Optimization with Enhanced ADTs
abstract: Object-relational queries access large complex data types and expensive methods of those data types. In earlier work, we modeled complex types as "Enhanced ADTs" (E-ADTs) and demonstrated the resulting performance improvements when implemented in the PREDATOR system. This paper explores the opportunities for further improvements through interactions between relational query optimization and E-ADT optimization. We identify four broad categories of optimization opportunities and study specific examples in each of these categories. These examples span query rewrite, indexing, aggregation and join optimization. Our conclusion is that non-trivial interactions exist between E-ADTs and relational queries, and that special optimization techniques are necessary to achieve good performance. These techniques have been prototyped in PREDATOR, and we present experimental results that demonstrate their effect.

title: Dynamical Automata
abstract: The recent work on automata whose variables and parameters are real numbers (e.g., Blum, Shub, and Smale, 1989; Koiran, 1993; Bournez and Cosnard, 1996; Siegelmann, 1996; Moore, 1996) has focused largely on questions about computational complexity and tractability. It is also revealing to examine the metric relations that such systems induce on automata via the natural metrics on their parameter spaces. This brings the theory of computational classification closer to theories of learning and statistical modeling which depend on measuring distances between models. With this in mind, I develop a generalized method of identifying pushdown automata in one class of real-valued automata. I show how the real-valued automata can be implemented in neural networks. I then explore the metric organization of these automata in a basic example, showing how it fleshes out the skeletal structure of the Chomsky Hierarchy and indicates new approaches to problems in language learning and language typology.

title: Dynamic Virtual Private Networks
abstract: We extend traditional Virtual Private Networks (VPNs) with fault-tolerance and dynamic membership properties, defining a Dynamic Virtual Private Network (DVPN). We require no new hardware and make no special assumptions about line security. An implementation exhibits low overheard, provides guarantees of authenticity and confidentiality to any IP application running over the virtual network. Our system is lightweight, allowing the use of multiple fine-grained VPNs. Instead of using many point-to-point secure connections to bridge insecure communication paths we share a single symmetric encryption key throughout the VPN. This permits tight control of the VPN membership and fast dynamic membership change. Since

we lower the cost of a single DVPN, we propose using multiple DVPNs to implement fine grained security. By enforcing policies over communication between DVPNs, our scheme supports multilevel security.

title: Availability and Consistency in a Partitionable Low Bandwidth Network
abstract: The Internet is a partitionable low bandwidth network. Two computers connected by the Internet could temporarily become unable to communicate for various reasons, from a failure at either end, to overloading of an intermediate node connecting the two, to an out-of-date routing table. The bandwidth of the Internet is relatively low: its data transfer speed is inadequate for applications that need to access very large data objects. Since its introduction the Internet kept a much faster rate of increase for the data available than for the data transfer speed. This trend is not likely to change any time soon. This thesis presents techniques to deal with availability and consistency in partitionable low bandwidth networks, and it presents a service suitable for use in such networks. The first part of the thesis presents replication techniques suitable in a partitionable network. A partitionable network puts goals of availability and consistency at odds. Making objects available in a partitionable network requires replication; yet modifications of replicated objects during a partition can introduce inconsistencies. We show various replication techniques that provide continuous availability while managing inconsistencies among replicas. The second part of the thesis describes the PEX system, an example of a service that instantiates these abstractions. PEX is an execution service that facilitates processing of remote data. It allows computations to be performed near data, so that data need not be copied over the network. It provides a session interface which facilitates the management of related computations operating on scattered data. Internally, PEX replicates various information, including sessions, using some of the techniques introduced in the first section of the thesis. This permits the system to keep computations running in the face of partitions. The third part of the thesis gives two example applications that use PEX (a distributed shell and a parallel make) and reports the performance of the PEX system.

title: Automatic Discovery of Logical Document Structure
abstract: The availability of large, heterogeneous repositories of electronic documents is increasing rapidly, and the need for flexible, sophisticated document manipulation tools is growing correspondingly. These tools can benefit greatly by exploiting logical structure, a hierarchy of visually observable organizational components of a document, such as paragraphs, lists, sections, em etc. Knowledge of this structure can enable a multiplicity of applications, including hierarchical browsing, structural hyperlinking, logical component-based retrieval, and style translation. Most work on the problem of deriving logical structure from document layout either relies on knowledge of the particular document style or finds a single flat set of text blocks. This thesis describes an implemented approach to discovering a full logical hierarchy in generic

text documents, based primarily on layout information. Since the styles of the documents are not known a priori, the precise layout effects of the logical structure are unknown. Nonetheless,typographical capabilities and conventions provide cues that can be used to deduce a logical structure for a generic document. In particular, the key idea is that analyses of the text contours at appropriate levels of granularity offer a rich source of information about document structure. The problem of logical structure discovery is divided into problems of segmentation, which separates the text into logical pieces, and classification, which labels the pieces with structure types. The segmentation algorithm relies entirely on layout-based cues, and the classification algorithm uses word-based information only when this is demonstrably unavoidable. Thus, this approach is particularly appropriate for scanned-in documents, since it is more robust with respect to OCR errors than a content-oriented approach would be. It is applicable, however, to the problem of analyzing any electronic document whose original formatting style rules remain unknown; thus, it can provide the basis for flexible document manipulation tools in heterogeneous collections.

title: Type-Theoretic Methodology for Practical Programming Languages
abstract: The significance of type theory to the theory of programming languages has long been recognized. Advances in programming languages have often derived from understanding that stems from type theory. However, these applications of type theory to practical programming languages have been indirect; the differences between practical languages and type theory have prevented direct connections between the two. This dissertation presents systematic techniques directly relating practical programming languages to type theory. These techniques allow programming languages to be interpreted in the rich mathematical domain of type theory. Such interpretations lead to semantics that are at once denotational and operational, combining the advantages of each, and they also lay the foundation for formal verification of computer programs in type theory. Previous type theories either have not provided adequate expressiveness to interpret practical languages, or have provided such expressiveness at the expense of essential features of the type theory. In particular, no previous type theory has supported a notion of partial functions (needed to interpret recursion in practical languages), and a notion of total functions and objects (needed to reason about data values), and an intrinsic notion of equality (needed for most interesting results). This dissertation presents the first type theory incorporating all three, and discusses issues arising in the design of that type theory. This type theory is used as the target of a type-theoretic semantics for a expressive programming calculus. This calculus may serve as an internal language for a variety of functional programming languages. The semantics is stated as a syntax-directed embedding of the programming calculus into type theory. A critical point arising in both the type theory and the type-theoretic semantics is the issue of admissibility. Admissibility governs what types it is legal to form recursive functions over. To build a useful type theory for partial functions it is necessary to have a wide class of admissible types. In particular, it is necessary for all the types arising in the type-theoretic semantics to be admissible. In this dissertation I present a class of admissible types that is considerably wider than any previously known class.

title: DENSITY ESTIMATION TECHNIQUES FOR GLOBAL ILLUMINATION
abstract: In this thesis we present the density estimation framework for computing view-independent global illumination solutions. The framework consists of three phases: particle tracing, density estimation, and

decimation. Monte Carlo particle tracing is used to accurately simulate the light transport under a general spectral geometric-optics based physical model. Next kernel density estimation is used to reconstruct perceptual illumination functions. Finally decimation is used to optimize the resulting mesh for compactness and rapid interactive display as Gouraud-shaded triangles. The three principal contributions of this work are the framework's separation of transport and function reconstruction computations, its ability to produce accurate solutions with precisely known error characteristics, and the techniques that we introduce to improve its efficiency and accuracy. Particle tracing's generality allows us to eliminate or delay many common simplifying assumptions and improves our accuracy and error analysis. Delaying the density estimation until particle tracing is complete allows us to make better use of the expensive particle data. The separation of global transport and local representation computations also reduces the computational complexity of each phase, enhances the framework's scalability, and exposes abundant opportunities for parallelism. Another advantage is that we can solve directly for the radiant exitance without needing to estimate the more complicated spectral radiance function. Despite its advantages, if naively implemented the framework would be prohibitively expensive. Thus we also introduce several techniques that significantly improve its accuracy and efficiency. These include the separation of luminance and chromaticity bandwidths, perceptually-motivated noise visibility predictors, statistical bias detection techniques to automatically enhance underresolved illumination features, a local polynomial density estimation method to eliminate boundary bias, and wavelength importance sampling to reduce the spectral noise. Results of the framework are shown for some complex environments and compared against measured data for a simple scene. The strength of our framework is that it can simulate a wider variety of lighting effects, with fewer simplifying assumptions, and more precise error analysis that current view-independent methods. Furthermore, because of its accuracy, our density estimation framework solutions are used as reference solutions for judging the quality and effectiveness of more approximate but faster rendering methods.

title: Segmentation of Pulmonary Nodule Images Using Total VariationMinimization
abstract: Total variation minimization has edge preserving and enhancing properties which make it suitable for image segmentation. We present Image Simplification, a new formulation and algo rithm for image segmentation. We illustrate the edge enhancing properties of total variation minimization in a discrete setting by giving exact solutions to the problem for piecewise constant functions in the presence of noise. In this case, edges can be exactly recovered if the noise is sufficiently small. After optimization, segmentation is completed using edge detection. We find that our image segmentation approach yields good results when applied to the segmentation of pulmonary nodules.

title: Fast Detection of Common Geometric Substructure in Proteins
abstract: We consider the problem of identifying common three-dimensional substructures between proteins. Our method is based on comparing the shape of the α-carbon backbone structures of the proteins in order to find 3D rigid motions that bring portions of the geometric structures into correspondence. We propose a geometric representation of protein backbone chains that is compact yet allows for similarity measures that are robust against noise and outliers. We represents the structure of the backbone as a sequence of unit vectors, defined by each adjacent pair of α-carbons; we then define a measure of the similarity of two protein structures based on the RMS (root mean squared) distance between corresponding orientation vectors in the two proteins. Our measure has several advantages over standard position-based RMS measures that are commonly used for comparing protein shapes. In particular, the measure behaves well for comparing substructures, because unlike position-based measures the nonmatching portions of the structure do not dominate the measure. At the same time, it avoids the quadratic space and computational difficulties associated with the use of distance matrices and contact maps. We show applications of our approach to detecting common contiguous substructures in pairs of proteins, as well as the more difficult problem of identifying common protein domains (i.e., larger substructures that are not necessarily contiguous along the protein chain).

title: Reconstructing the unknown volatility function
abstract: Using market European option prices, a method for computing a {\em smooth} local volatility function in a 1-factor continuous diffusion model is proposed. Smoothness is introduced to facilitate accurate approximation of the true local volatility function from a finite set of observation data. It is emphasized that accurately approximating the true local volatility function is crucial in hedging even simple European options, and pricing exotic options. A spline functional approach is used: the local volatility function is represented by a spline whose values at chosen knots are determined by solving a constrained nonlinear optimization problem. The optimization formulation is amenable to various option evaluation methods; a partial differential equation implementation is discussed. Using a synthetic European call option example, we illustrate the capability of the proposed method in reconstructing the unknown local volatility function. Accuracy of pricing and hedging is also illustrated. Moreover, it is demonstrated that, using a different constant implied volatility for an option with different strike/maturity can produce erroneous hedge factors. In addition, real market European call option data on the S and P 500 stock index is used to compute the local volatility function; stability of the approach is demonstrated.

title: Formal Reasoning about Communication Systems II: Automated Fast-TrackReconfiguration
abstract: We present formal techniques for improving the performance of group communication systems built with the Ensemble toolkit. For common sequences of operations we identify a fast-track through a stack of communication protocols and reconfigure the system's code accordingly. Our techniques are implemented as fully automated tactics of the NuPRL proof development system and are based on an embedding the implementation language of Ensemble into the logical language of NuPRL. Together with verification techniques to be developed in the near future they will lead to a logical programming environment for the construction of reliable and efficient group communication systems.

title: A Software Architecture for Zero-Copy RPC in Java
abstract: RPC has established itself as one of the more powerful communication paradigms for distributed computing. In recent years, object-oriented languages have impacted RPC semantics, with a number of variants providing remote method invocation and various forms of distributed object systems. At the same time, performance has changed little with the bottleneck being the network transport, in particular the in-kernel protocol implementations. This paper describes J-RPC, an RPC architecture that leverages user-level network interfaces (UNI) to circumvent the kernel on the critical path. It describes how the wire format and the RPC system can be engineered to allow zero-copy reception of Java objects and zero-copy transmission of arrays. All objects received are fully type-checked and can be directly used by the receiving program. The design is connection-oriented for performance and leverages the JVM's garbage collector when managing receive buffers. An implementation built from an off-the-shelf JVM and a commercial UNI is used to evaluate

the architecture and the tradeoffs of type-safe, zero-copy data marshaling.

title: Formalizing Reference Types in NuPRL, PhD Thesis
abstract: This dissertation defines a Type Theory based semantics for Java-like reference type constructors. The primary focus is made on finding an adequate axiomatization of reference types in Type Theory. An extension of Type Theory, called {\em Reference Type Theory}, is introduced. It adds to the Type Theory language a reference type constructor and operations on reference type elements as primitive notions. The dissertation provides informal graph-based semantics for the Reference Type Theory, describes inference rules for this theory, and proves their consistency. Reference Type Theory is formalized in the Nuprl Proof Development System. This formalization is used to define a formal semantics for a fragment of the Java programming language and to verify several simple Java programs.

title: On the Structure of Syntenic Distance
abstract: This paper examines some of the rich structure of the syntenic distance measure of the evolutionary distance between genomes. This model, introduced by Ferretti, Nadeau, and Sankoff, abstracts away from the order of genes, and considers chromosomes as unordered sets of genes. The syntenic distance between two genomes is given by the minimum number of moves (fusing two chromosomes, fissioning one chromosome, or completing a reciprocal translocation between two chromosomes) required to transform one into the other. We consider previously unanalyzed approximation algorithm given by Ferretti et al, and prove that it is in fact a 2-approximation and that, further, it outperforms the algorithm presented by DasGupta et al on all instances. We prove a number of properties which give insight into the structure of optimal move sequences. We prove a monotonicity property for the syntenic distance, and give bounds on the number of moves required to solve the hardest instance of any given size. We then demonstrate that there exist instances in which any move sequence working solely within connected components is $2 - \epsilon$ times longer than optimal, which indicates that all previously proposed approximation algorithms can be no better than 2-approximations.

title: Clustered File Generation and Its Application to Computer Science Taxonomies
abstract: A clustered file organization is one where related, or similar records are grouped into classes, or clusters of items in such a way that all items within a cluster are jointly retrievable. Such a file organization is advantageous for interactive searching where tentative query formulations may be used and the records may be specified incompletely or approximately. An inexpensive file clustering method applicable to large files is given together with an appropriate file search method. The method is used to cluster a file of research articles in computer science based on citation similarities between the papers; this leads to the identification of groups of active computer science research topics and of productive computer scientists.

title: A New Bayesian Framework for Object Recognition
abstract: We describe a new approach to feature-based object recognition, using maximum a posteriori (MAP) estimation under a Markov random field (MRF) model. The main advantage of this approach is that it allows explicit modeling of dependencies between individual features of an object. For instance, we use the approach to model the fact that mismatched features due to partial occlusions tend to form spatially coherent groups rather than being independent. Efficient computation of the MAP estimate in our framework can be accomplished by finding a minimum cut on an appropriately defined graph. An even more efficient approximation, that does not use graph cuts, is also presented. This approximation technique, which we call spatially coherent matching (SCM), is closely related to generalized Hausdorff matching. We report some Monte Carlo experiments showing that the SCM technique improves substantially on the tradeoff between correct detection and false alarms compared with previous feature matching methods such as the Hausdorff distance.

title: Efficient Algorithms for Protein Sequence Design and the Analysis ofCertain Evolutionary Fitness Landscapes
abstract: Protein sequence design is a natural inverse problem to protein structure prediction: given a target structure in three dimensions, we wish to design an amino acid sequence that is likely fold to it. A model of Sun, Brem, Chan, and Dill casts this problem as an optimization on a space of sequences of hydrophobic (H) and polar (P) monomers; the goal is to find a sequence which achieves a dense hydrophobic core with few solvent-exposed hydrophobic residues. Sun et al. developed a heuristic method to search the space of sequences, without a guarantee of optimality or near-optimality; Hart subsequently raised the computational tractability of constructing an optimal sequence in this model as an open question. Here we resolve this question by providing an efficient algorithm to construct optimal sequences; our algorithm has a polynomial running time, and performs very efficiently in practice. We illustrate the implementation of our method on structures drawn from the Protein Data Bank. We also consider extensions of the model to larger amino acid alphabets, as a way to overcome the limitations of the binary H/P alphabet. We show that for a natural class of arbitrarily large alphabets, it remains possible to design optimal sequences efficiently. Finally, we analyze some of the consequences of this sequence design model for the study of evolutionary fitness landscapes. A given target structure may have many sequences that are optimal in the model of Sun et al.; following a notion raised by the work of J. Maynard Smith, we can ask whether these optimal sequences are ``connected'' by

successive point mutations. We provide a polynomial-time algorithm to decide this connectedness property, relative to a given target structure. We develop the algorithm by first solving an analogous problem expressed in terms of submodular functions, a fundamental object of study in combinatorial optimization.

title: Design and Evaluation of an Extensible Web and Telephony Server based on the J-Kernel
abstract: This paper describes the design and performance of the J-Server, an integrated web and telephony server that allows untrusted Java servlets to be dynamically uploaded to extend the server's functionality. The J-Kernel provides for protection and communication between J-Server servlets, and ensures that servlets can be cleanly terminated. A resource monitor called JRes is used to account for servlet resource usage. Two sample applications show that the overhead of J-Kernel task boundary crossings is small compared to the applications' overall running time. Experience developing applications for the J-Server demonstrates the benefits of extensible systems based on safe language protection, and the flexibility of the servlet model.

title: Critical Infrastructures You Can Trust: Where Telecommunications Fits
abstract: This paper discusses two NISs: the public telephone network (PTN) and the Internet. Being themselves large and complex NISs, they not only merit study in their own right but can help us to understand some of the technical problems faced by the developers and operators of other NISs. In addition, the high cost of building a global communications infrastructure from the ground up implies that one or both of these two networks is likely to furnish communications services for most other NISs. Therefore, an understanding of the vulnerabilties of the PTN and Internet informs the assessment of the trustworthiness of other NISs. Ideas for improving the trustworthiness of the PTN and Internet are also proposed, both for the short-term (by improved use of existing technologies and procedures) and for the long-term (by identifying some areas where the state-of-the-art is inadequate and research is therefore needed). Finally, some observations are offered about Internet telephony and the use of the Internet for critical infrastructures.

title: Resource Control for Database Extensions
abstract: While object-relational database servers can be extended with user-defined functions (UDFs), the

security of the server may be compromised by these extensions. The use of Java to implement the UDFs is promising because it addresses some security concerns. However, it still permits interference between different users through the uncontrolled consumption of resources. In this paper, we explore the use of a Java resource management mechanism (JRes) to monitor resource consumption and enforce usage constraints. JRes enhances the security of the server in the presence of extensions allowing for (i) detection and neutralization of denial-of-service attacks aimed at resource monopolization, (ii) monitoring resource consumption which enables precise billing of users relying on UDFs, and (iii) obtaining feedback that can be used for adaptive query optimization. The feedback can be utilized either by the UDFs themselves or by the database system to dynamically modify the query execution plan. Both models have been prototyped in the Cornell Predator database system. We describe the implementation techniques, and present experiments that demonstrate the effects of the adaptive behavior facilitated by JRes. We conclude that, minimally, a database system supporting extensions should have a built-in resource monitoring and controlling mechanism. Moreover, in order to fully exploit information provided by the resource control mechanisms, both the query optimizer and the UDFs themselves should have access to this information.

title: Client-Site Query Extensions
abstract: We explore the execution of queries with client-site user-defined functions (UDFs). Many UDFs can only be executed at the client site, for reasons of scalability, security, confidentiality, or availability of resources. How should a query with client-site UDFs be executed? We demonstrate that the standard execution technique for server-site UDFs performs poorly. Instead, we adapt well-known distributed database algorithms and apply them to client-site UDFs. The resulting query execution techniques are implemented in the Cornell Predator database system, and we present performance results to demonstrate their effectiveness. We also reconsider the question of query optimization in the context of client-site UDFs. The known techniques for expensive UDFs are inadequate because they do not take the location of the UDF into account. We present an extension of traditional 'System-R' optimizers that suitably optimize queries with client-site operations.

title: A Compression Framework for Query Results
abstract: Decision-support applications in emerging environments require that entire SQL query results be shipped to clients for further analysis and presentation. These clients may use low bandwidth connections (like modems) or have severe memory restrictions (like palmtops). Consequently, there is a need to compress the results of a query for efficient transfer and client-side storage. This paper explores a variety of techniques that address this issue. We model the problem as the choice of an appropriate compression plan and present a framework to model acceptable compression plans. The factors that influence this choice include schema information and statistics on stored tables. Importantly, we demonstrate that the query itself and its evaluation plan can provide semantic information that can be used to compress the result. We demonstrate that these techniques can result in 75% greater compression than standard compression tools like WinZip on queries adapted from the TPC-D benchmark. We identify two topics for future research: the choice of an optimal compression plan, and the integration of query result compression into the regular query evaluation plan.

title: Intensional Polymorphism in Type-Erasure Semantics
abstract: Intensional polymorphism, the ability to dispatch to different routines based on types at run time, enables a variety of advanced implementation techniques for polymorphic languages, including tag-free garbage collection, unboxed function arguments, polymorphic marshalling, and flattened data structures. To date, languages that support intensional polymorphism have required a type-passing (as opposed to type-erasure) interpretation where types are constructed and passed to polymorphic functions at run time. Unfortunately, type-passing suffers from a number of drawbacks: it requires duplication of constructs at the term and type levels, it prevents abstraction, and it severely complicates polymorphic closure conversion. We present a type-theoretic framework that supports intensional polymorphism, but avoids many of the disadvantages of type passing. In our approach, run-time type information is represented by ordinary terms. This avoids the duplication problem, allows us to recover abstraction, and avoids complications with closure conversion. In addition, our type system provides another improvement in expressiveness; it allows unknown types to be refined in place thereby avoiding certain beta-expansions required by other frameworks.

title: Decidability Extracted: Synthesizing "Correct-by-Construction" DecisionProcedures from Constructive Proofs
abstract: The topic of this thesis is the extraction of efficient and readable programs from formal constructive proofs of decidability. The proof methods employed to generate the efficient code are new and result in clean and readable Nuprl extracts for two non-trivial programs. They are based on the use of Nuprl's set type and techniques for extracting efficient programs from induction principles. The constructive formal theories required to express the decidability theorems are of independent interest. They formally circumscribe the mathematical knowledge needed to understand the derived algorithms. The formal theories express concepts that are taught at the senior college level. The decidability proofs themselves, depending on this material, are of interest and are presented in some detail. The proof of decidability of classical propositional logic is relative to a semantics based on Kleene's strong three-valued logic. The constructive proof of intuitionistic decidability presented here is the first machine formalization of this proof. The exposition reveals aspects of the Nuprl tactic collection relevant to the creation of readable proofs; clear extracts and efficient code are illustrated in the discussion of the proofs.

title: Parikh's Theorem in Commutative Kleene Algebra
abstract: Parikh's Theorem says that the commutative image of every context free language is the commutative image of some regular set. Pilling has shown that this theorem is essentially a statement about least solutions of polynomial inequalities. We prove the following general theorem of commutative Kleene algebra, of which Parikh's and Pilling's theorems are special cases: Every system of polynomial inequalities $f_i(x_1,\ldots,x_n) \leq x_i$, $1\leq i\leq n$, over a commutative Kleene algebra K has a unique least solution in K^n; moreover, the components of the solution are given by polynomials in the coefficients of the f_i. We also give a closed-form solution in terms of the Jacobian matrix.

title: A Characterization Study of NCSTRL Distributed Searching
abstract: NCSTRL, the Networked Computer Science Technical Reference Library, is a federated digital library based on the Dienst architecture. One aspect of this architecture is distributed searching, with digital library queries being dispatched from query routers to globally distributed indexers that process them and return results. We studied user data for a two-month period at five query routers in order to characterize some key performance aspects of distributed searching in an operational digital library. This study uncovered the following characteristics. Query processing at NCSTRL servers involves significant time waiting for responses from indexers. Each indexer's availability and response times appear unique to each query router. Different indexers' availability and response times are not similar from the viewpoint of a single query router. Query router waiting time for indexers is larger than indexer processing time, implying that communication time over the network is significant. We close by examining the breakdown of NCSTRL queries: the number of fielded vs. non-fielded queries, and the complexity of these queries.

title: A Review of Experiences with Reliable Multicast
abstract: By understanding how real users have employed reliable multicast in real distributed systems, we can develop insight concerning the degree to which this technology has matched expectations. This paper reviews a number of applications with that goal in mind. Our findings point to tradeoffs between the form of reliability used by a system and its scalability and performance. We also find that to reach a broad user community (and a commercially interesting market) the technology must be better integrated with component and object-oriented systems architectures. Looking closely at these architectures, however, we identify some assumptions about failure handling which make reliable multicast difficult to exploit. Indeed, the major failures of reliable multicast are associated with attempts to position it within object oriented systems in ways that focus on transparent recovery from server failures. The broader opportunity appears to involve relatively visible embeddings of these tools into object-oriented architectures enabling knowledgeable users to make tradeoffs. Fault-tolerance through transparent server replication may be better viewed as an unachievable holy grail.

title: Interfacing Java with the Virtual Interface Architecture
abstract: User-level network interfaces (UNIs) have reduced the overheads of communication by exposing the buffers used by the network interface DMA engine to the applications. This removes the kernel from the critical path of message transmission and reception, and it reduces the number of data copies performed on that path. Unfortunately, the fact that UNIs require the application to manage buffers explicitly makes it difficult to provide direct access to a UNI from Java, as the language explicitly prevents programs from controlling the location or layout of objects. This paper describes Javia, a Java interface to the Virtual Interface Architecture (VIA), an emerging UNI standard in the industry. Javia implements a special buffer abstraction that allows Java programs to allocate arrays in pinned memory and use them as communication buffers without copy. The location and lifetime of these arrays are controlled through small modifications to the garbage collector. Simple experiments show that Java programs can achieve round-trip times of 21us for small messages and bandwidths of 95Mbytes/sec for 4Kbyte messages.

title: Efficient and Accurate Ethernet Simulation
abstract: The Internet is increasingly being called upon to provide different levels of service to different applications and users. A practical problem in doing so is that although Ethernet is one of the hops for nearly all communication in the Internet, it does not provide any QoS guarantees. A natural question, therefore, is the effect of offered load on Ethernet throughput and delay. In this paper, we present several techniques for accurately and quickly modeling the behavior of a heavily loaded Ethernet link. We first present a distributed approach to exact simulation of Ethernet, which eliminates sophisticated collision detection. Then, we describe an efficient distributed simulation model, called Fast Ethernet Simulation, that empirically models an Ethernet link to quickly and accurately simulate it. By eliminating the implementation of CSMA/CD protocol, our approach reduces computational complexity drastically while still maintaining desirable accuracy. Performance results show that our techniques not only add very little overhead (less than 5 in our tests) to the basic cost of simulating an Ethernet link, but also closely match real-world mesurements. We also present efficient techniques for compressing cumulative distributions using hyperbolic curves and for monitoring the load on a heavily-loaded link.

title: Detecting Static Objects in Busy Scenes

abstract: Detecting static objects in scenes containing significant number of moving objects has several applications in video surveillance. One example is the detection of suspicious packages which is left unattended in an airport terminal or railway station. This paper outlines an approach to automatically detect static objects from a video sequence of a busy scene. Our approach consists of two phase : foreground object extraction and object matching. In the first phase, we find the foreground objects in current video frame, using an image of a background as reference. In the object matching phase, we try to match the objects with objects that appears before in previous frames. Matching is done based on three parameter : shape and position, intensity and edge. Temporary occluded of objects is also handled. We built a system based on our approach. Preliminary experiments shows that our system are able to identify static objects in a busy scene in real time.

title: Optimizing TCP Start-up Performance
abstract: The performance of many networking protocols is dependent on a handful of tuning parameters. However, it is not obvious how to set or adapt these parameters to optimize performance. We believe that this optimization task can benefit from passive monitoring of current network performance. In this paper, we apply this methodology for initializing TCP parameters, such as initial congestion window size and slow start threshold for short connections. We analytically derive the optimal initial parameters, and use simulations to study its effectiveness. Our innovations include: (i) derivation of optimal TCP initial parameters as a function of link characteristics; (ii) abstract a communication path as a virtual link and model cross traffic as perturbation on it; (iii) an efficient architecture for network performance discovery; (iv) a new pacing algorithm that combines leaky bucket flow control with traditional window-based flow control. Our results show this approach leads to significant performance improvement.

title: Relational Algebraic Techniques for the Synthesis of Sparse MatrixPrograms
abstract: Sparse matrix computations are ubiquitous in computational science. However, the development of high-performance software for sparse matrix computations is a tedious and error-prone task, for two reasons. First, there is no standard way of storing sparse matrices, since a variety of formats are used to avoid storing zeros, and the best choice for the format is dependent on the problem and the architecture. Second, for most algorithms, it takes a lot of code reorganization to produce an efficient sparse program that is tuned to a particular format. We view the problem of supporting effective development of high-performance sparse matrix codes as one of {\em generic programming}. Generic programming is a discipline of designing and implementing software components which can be used when there is a set of {\em related data structures} supporting a common semantics described by an API or protocol, and a set of {\em common algorithms} that can be formulated in terms of this API. When designing a generic programming system one must address the following fundamental questions: -- How do we represent efficient algorithms independently of any particular data-representation scheme? -- How do we provide an interface to a diverse set of data-structures? -- How do we ``knit'' together the representation of the algorithms and the representation for the data to obtain an efficient implementation? This dissertation presents a {\em relational algebraic model} for automatically generating efficient sparse codes starting with dense matrix codes and specification of sparse matrix formats. Our techniques are based on viewing arrays as relations and the execution of DOALL loop

nests and loops with reductions as evaluation of queries over these relations. Storage formats are specified to the compiler through search and enumeration access methods and their costs. Code restructuring is then formulated as the search for the most efficient plan for the query. The main step in this process is the identification of simultaneous enumeration of data structures (relational joins) and the determination of the best implementations of this enumeration. This software architecture not only provides for a clean design of the compiler, but it also exposes additional opportunities for code optimization and has led us to more general transformation algorithms than previously reported in the literature. We present experimental data that demonstrates that the code generated by our compiler achieves performance competitive with that of hand-written codes for important computational kernels.

title: Insight into Theorem Proving via Eye Movements
abstract: We are implementing an automated theorem proving system that will in part attempt to simulate human per-formance on calculational logic. To support this project, we recorded and analyzed people's eye movements while they constructed calculational proofs. Our find-ings confirm some expected behaviors (based on strate-gies and principles taught to students) that previously may have seemed untestable, such as the influence of the form of the current proof step and of syntax in gen-eral on the moment-by-moment computations of the problem solver. The experiment also uncovered other interesting patterns, such as the seemingly inefficient but widely occurring tendency to attend to particular premises despite their not being used in the proof under consideration. Overall, we gained insights into real-time problem solving that directly apply to our automated system and could not have been gained merely by studying written proofs. Our findings also demonstrate that analyses of eye movements can improve our under-standing of the psychology of theorem proving.

title: Type Dispatch for Named Hierarhical Types
abstract: Type dispatch constructs are an important feature of many programming languages. Scheme has predicates for testing the runtime type of a value. Java has a class cast expression and a try statement for switching on an exception's class. Crucial to these mechanisms, in typed languages, is type refinement: The static type system will use type dispatch to refine types in successful dispatch branches. Existing work in functional languages has addressed certain kinds of type dispatch, namely, intensional type analysis. However, this work does not extend to languages with subtyping nor to named types. This paper describes a number of type dispatch constructs that share a common theme: class cast and class case constructs in object oriented languages, ML style exceptions, hierarchical extensible sums, and multimethods. I describe a unifying mechanism, {\em tagging}, that abstracts the operation of these constructs, and formalise a small tagging language. After discussing how to implement the tagging language, I present a more primitive language and give a formal translation from the tagging language.

title: A Multicast Flow Control Protocol
abstract: This paper describes the goals, approach, implementation, and performance of Mflow, a multicast flow control protocol. Our work focuses on the issues that arise from the increase in acknowledgments that occur as the size of the group grows. Mflow makes use of bulk acknowledgments to substantially reduce

the number of acknowledgments per multicast message. It also staggers acknowledgments from different destinations to avoid storms of messages. We demonstrate that staggering can both decrease the number of acknowledgments needed for effective flow control as well as increase the robustness of the protocol to changes in the environment. We analyze both message and computation efficiency of Mflow. The protocol is computationally efficient and performs well in our experiments.

title: A Type System for Expressive Security Policies
abstract: {\em Certified code} is a general mechanism for enforcing security properties. In this paradigm, untrusted agent code carries annotations that allow a host to verify its trustworthiness. Before running the agent, the host checks the annotations and proves that they imply the host's security policy. Despite the flexibility of this scheme, so far, compilers that generate proof-carrying code have focused on simple memory and control-flow safety rather than more general security properties. {\em Security automata} can enforce an expressive collection of security policies including access control policies and resource bounds policies. In this paper, we show how to take specifications in the form of security automata and automatically transform them into signatures for a typed lambda calculus that will enforce the corresponding safety property. Moreover, we describe how to instrument typed source language programs with security checks and typing annotations so that the resulting programs are provably secure and can be mechanically checked. This work provides a foundation for the process of automatically generating secure certified code in a type-theoretic framework.

title: Revisiting the Weakest Failure Detector for Uniform Reliable Broadcast
abstract: Uniform Reliable Broadcast (URB) is a communication primitive that requires that if a process delivers a message, then all correct processes also deliver this message. A recent PODC paper [HR99] uses Knowledge Theory to determine what failure detectors are necessary to implement this primitive in asynchronous systems with process crashes and lossy links that are fair. In this paper, we revisit this problem using a different approach, and provide a result that is simpler, more intuitive, and, in a precise sense, more general.

title: Predicting Indexer Performance in a Distributed Digital Library
abstract: Resource discovery in a distributed digital library poses many challenges, one of which is how to choose search engines for query distribution, given a query and a set of search engines. This paper focuses on search engine performance as a criterion for search engine selection and defines two measurements of search engine performance: availability - will the search engine respond within a time limit and response time - how quickly will the search engine respond, given that it responds at all. We predicted both of these performance characteristics with a variety of algorithms, all of which required little computation time and combined past performance data for each search engine into a succinct record. We used operational data from the NCSTRL distributed digital library to make and evaluate predictions, and we found that simple prediction methods performed as well as more complex methods and that prediction accuracy was closely related to data consistency.

title: On Individual and Aggregate TCP Performance
abstract: As the most widely used reliable transport in today's Internet, TCP has been extensively studied in the past decade. However, previous research usually only considers a small or medium number of concurrent TCP connections. The TCP behavior under many competing TCP flows has not been sufficiently explored. In this paper we use extensive simulations to investigate the individual and aggregate TCP performance for large number of concurrent TCP flows. We have made three major contributions. First, we develop an abstract network model that captures the essence of wide-area Internet connections. Second, we study the performance of a single TCP flow with many competing TCP flows by evaluating the best-known analytical model proposed in the literature. Finally, we examine the aggregate TCP behavior exhibited by many concurrent TCP flows, and derive general conclusions about the overall throughput, goodput, and loss probability.

title: Bimodal Multicast (revised)
abstract: There are many methods for making a multicast protocol "reliable". At one end of the spectrum, a reliable multicast protocol might offer atomicity guarantees, such as all-or-nothing delivery, delivery ordering, and perhaps additional properties such as virtually synchronous addressing. At the other are protocols that use local repair to overcome transient packet loss in the network, offering 'best effort' reliability. Yet none of this prior work has treated stability of multicast delivery as a basic reliability property, such as might be needed in an internet radio, TV, or conferencing application. This paper looks at reliability with a new goal: development of a multicast protocol which is reliable in a sense that can be rigorously quantified and includes throughput stability guarantees. We characterize this new protocol as a "bimodal multicast" in reference to its reliability model, which corresponds to a family of bimodal probability distributions. Here, we introduce the protocol, provide a theoretical analysis of its behavior, review experimental results, and discuss some candidate applications. These confirm that bimodal multicast is reliable, scalable, and that the protocol provides remarkably stable delivery throughput.

title: Programming Language Translation
abstract: As programming languages become more and more diversified, there is an increasing demand to translate programs written in one high-level language into another. Such translation can help us more effectively reuse the existing code, especially when automating translation is possible. However due to many subtle distinctions between different languages, usually only a subset of translation can be automated. The first half of the paper describes the details of automating most of the translation from C to C++, as well as the difficulties encountered. The second half of the paper talks about the experience of manually porting Java programs to C++, and identifies some of the issues and challenges in automating this translation process. Through the discussions, it is evident that translation is heavily language specific. Comprehensive knowledge about the languages and their subtle distinctions is essential. On the other hand, designing tools to allow high level specification of translation rules and effectively incorporate human interaction is a generic approach to any language translation problem, which is an interesting research problem to explore.

title: Scalability of Two Reliable Multicast Protocols
abstract: Growing demand for multicast commun-ication in large network settings has focused attention on the scalability of reliable multicast protocols. Our paper uses both simulation tools and experiments to compare two scalable protocols, focusing on an aspect not often studied: we emphasize stability of latency distributions as these protocols scale, although also considering overhead and link utilization. These properties are considered in a variety of network topologies and with several levels of packet loss. Our findings confirm that SRM scales poorly under some conditions: to obtain reliability, the protocol incurs overhead linear in group size and throughput fluctuates erratically. We also show that SRM latencies can be very large and that latency distributions are unstable as a function of group size and network topology. Our own protocol, Bimodal Multicast, also exhibits overhead growth, but the rate of growth is slow, and latency distributions and delivery throughput rates are stable.

title: Efficient and Accurate Ethernet Simulation (revised)
abstract: The Internet is increasingly being called upon to provide different levels of service to different applications and users. A practical problem in doing so is that although Ethernet is one of the hops for nearly all communication in the Internet, it does not provide any QoS guarantees. A natural question, therefore, is the effect of offered load on Ethernet throughput and delay. In this paper, we present several techniques for accurately and efficiently modeling the behavior of a heavily loaded Ethernet link. We first present a distributed approach to exact simulation of Ethernet. Then, we describe an efficient distributed simulation model, called Fast Ethernet Simulation, that empirically models an Ethernet link to quickly and accurately simulate it. By eliminating the implementation of CSMA/CD protocol, our approach reduces computational complexity drastically while still maintaining desirable accuracy. Performance results show that our techniques not only add very little overhead (less than 5% in our tests) to the basic cost of simulating an Ethernet link, but also closely match real-world measurements. We also present efficient techniques for compressing cumulative distributions using hyperbolic curves and for monitoring the load on a heavily loaded link. Finally, we show applications to illustrate the potential usage of the Fast Ethernet Simulation.

title: Pervasive Query Processing
abstract: We propose a radical departure from the architecture of conventional server-centered database query processing systems. Instead, we propose pervasive query processing on every component of the system: the server, the clients, and the storage components. The demands of modern applications and the current technology trends suggest that it is a significant limitation to require that all query processing is confined to the server. Consequently, we develop an architecture that is based on query processing engines that are integrated on every site of the database system. These software platforms that allow the execution of portable database programs on a variety of underlying physical platforms are called Database Virtual Machines.

title: Language-Based Security
abstract: Security of mobile code is a major issue in today's global computing environment. When you download a program from an untrusted source, how can you be sure it will not do something undesirable? In this paper I will discuss a particular approach to this problem called language-based security. In this approach, security information is derived from a program written in a high-level language during the compilation process and is included in the compiled object. This extra security information can take the form of a formal proof, a type annotation, or some other form of certificate or annotation. It can be downloaded along with the object code and automatically verified before running the code locally, giving some assurance against certain types of failure or unauthorized activity. The verifier must be trusted, but the compiler, code, and certificate need not be. Java bytecode verification is an example of this approach. I will give an overview of some recent work in this area, including a particular effort in which we are trying to make the production of certificates and the verification as efficient and invisible as possible.

title: Principals in Programming Languages: Technical Results
abstract: This is the companion technical report for ``Principals in Programming Languages'' [20]. See that document for a more readable version of these results. In this paper, we describe two variants of the simply typed $\lambda$-calculus extended with a notion of {\em principal}. The results are languages in which intuitive statements like ``the client must call $\mathtt{open}$ to obtain a file handle'' can be phrased and proven formally. The first language is a two-agent calculus with references and recursive types, while the second language explores the possibility of multiple agents with varying amounts of type information. We use these calculi to give syntactic proofs of some type abstraction results that traditionally require semantic arguments.

title: The Implication of Network Performance on Service Quality
abstract: As the Internet infrastructure evolves to include Quality of Service (QoS), it is necessary to map application quality requirements to the the network performance specifications in terms of delay and loss rate. While past work has addressed the dependency of audio and video applications on these underlying QoS metrics, little work has been done in the area of Web traffic. In this paper, we use a combination of emulation, simulation, and analysis to quantify the effect of network performance metrics on HTTP request latency and the perceptual quality of an audio application. Although our work is done in the context of a LAN environment, the results generalize to a more general WAN environment. Our contributions are three-fold. First, we combine simulation and emulation techniques in setting up an accurate yet controllable testbed. The use of network simulator Entrapid and its built-in Fast Ethernet Simulation makes our simulation both efficient and accurate. Second, for Web applications, we define a new TCP short connection model that computes the latency of Web retrieval accurately and efficiently given only packet delay and loss rate characteristics apriori. Experiments show that our model significantly improves the accuracy of the best-known TCP short connection model by correctly capturing TCP retransmission behavior. Finally, for Internet telephony, we show that the packet delay variance is the dominant network characteristics which affect the perceptual quality. As a result, the service quality drops dramatically when the Ethernet offered load reaches 80%. This can serve as a guideline for studies towards improving service quality of Internet telephony.

title: A Generic Programming System for Sparse Matrix Computations
abstract: Sparse matrices are stored in compressed formats in which zeros are not stored explicitly. Writing high-performance sparse matrix libraries is a difficult and tedious job because there are many compressed formats in use and each of them requires specialized code. In this paper, we argue that (i) compressed formats should be viewed as {\em indexed-sequential access structures} (in the database sense), and (ii) efficient sparse codes exploit such indexing structures wherever possible. This point of view leads naturally to restructuring compiler technology that can be used to synthesize many sparse codes from high-level algorithms and specifications of sparse formats, exploiting indexing structures for efficiency. We show that appropriate

abstractions of the indexing structures of commonly used formats can be provided to such a compiler through the type structure of a language like C++. Finally, we describe experimental results obtained from the {\em Bernoulli Sparse Compiler} which demonstrate that the performance of code generated by this compiler is comparable to the performance of programs in the NIST Sparse BLAS library. One view of this system is that it exploits restructuring compiler technology to perform a novel kind of template instantiation.

title: Efficient Buffering in Reliable Multicast Protocols
abstract: Reliable multicast protocols provide all-or-none delivery to participants. Traditionally, such protocols suffer from large buffering requirements, as receivers have to buffer messages, and buffer sizes grow with the number of participants. In this paper, we describe an optimization that allows such protocols to reduce the amount of buffering drastically at the cost of a very small probability that all-or-none delivery is violated. We analyze this probability, and simulate an optimized version of an epidemic multicast protocol to validate the effectiveness of the optimization. We find that the buffering requirements are sub-constant, that is, the requirements shrink with group size, while the probability of all-or-none violation can be set to very small values.

title: A Bayesian Framework for Model Based Tracking
abstract: We present a Bayesian framework for tracking an object in a sequence of image frames. A maximum a posteriori (MAP) recognition method is used to detect the object in each image frame, and a Kalman filter is used to estimate the true location from these observed locations. There is a natural feedback loop between the recognition method and the Kalman filter. The recognition method requires a prior on object location which is provided by the Kalman filter, and the Kalman filter requires an observed location which is provided by the recognition method. This framework has two desirable properties. First, the threshold for recognition in each frame depends on the system noise of the Kalman filter. This allows the system to identify partially occluded or distorted objects as long as the predicted locations are accurate. But requires a very good match if there is uncertainty as to the object location. Second, the search area for the recognition method is adaptively pruned using the current level of noise in the system, yielding an efficient overall method. Promising experimental results are demonstrated.

title: Object Closure Conversion
abstract: An integral part of implementing functional languages is closure conversion-the process of converting code with free variables into closed code and auxiliary data structures. Closure conversion has been extensively studied in this context, but also arises in languages with first-class objects. In fact, one variant of Java's inner classes are an example of objects that need to be closure converted, and the transformation for converting these inner classes into Java Virtual Machine classes is an example of closure conversion. This paper argues that a direct formulation of object closure conversion is interesting and gives further insight into general closure conversion. It presents a formal closure-conversion translation for a second-order object language and proves it correct. The translation and proof generalise to other object-oriented languages, and the paper gives some examples to support this statement. Finally, the paper discusses the well known connection between function closures and single-method objects. This connection is formalised by showing that an encoding of functions into objects, object closure conversion, and various object encodings compose to give various closure-conversion translations for functions.

title: Safe and Efficient Cluster Communication in Java using Explicit MemoryManagement
abstract: This thesis presents a framework for using explicit memory management to improve the communication performance of JavaTM cluster applications. The framework allows programmers to explicitly manage Java communication buffers, called jbufs, which are directly accessed by the DMA engines of high-performance network interfaces and by Java programs as primitive-typed ar-rays. The central idea is to remove the hard separation between Java's gar-bage-collected heap and the non-collected memory region in which DMA buffers must normally be allocated. The programmer controls when a jbuf is part of the garbage-collected heap so that the garbage collector can ensure it is safely re-used or de-allocated, and when it is not so it can be used for DMA transfers. Unlike other techniques, jbufs preserve Java's storage- and type-safety and do not depend on a particular garbage collection scheme. The safety, efficiency, and programmability of jbufs are demonstrated throughout this thesis with implementations of an interface to the Virtual In-terface Architecture, of an Active Messages communication layer, and of Java Remote Method Invocation (RMI). The impact on applications is also evalu-ated using an implementation of cluster matrix multiplication as well as a publicly available RMI benchmark suite. The thesis proposes in-place object de-serialization (de-serialization with-out allocation and copying of objects) to further enhance the performance of RMI on homogeneous clusters. This optimization takes advantage of the zero-copy capabilities of network devices to reduce the per-object de-serialization costs to a constant irrespective of object size, which is particularly beneficial for large objects such as arrays. In-place de-serialization is realized using jstreams, an extension of jbufs with object I/O streams. Jstreams use the ex-plicit memory management offered by jbufs to incorporate de-serialized

ob-jects into the receiving Java virtual machine without compromising its integrity, without restricting the usage of those objects, and without making assumptions about the underlying garbage collection scheme. The perform-ance impact of jstreams on Java RMI and the benchmark suite is evaluated.

title: A Scalable Efficient Robust Adaptive (SERA) Architecture for the NextGeneration of Web Service
abstract: The World Wide Web can be considered as a large distributed information system that provides access to shared data objects. As one of the most popular applications currently running on the Internet, the World Wide Web is of an exponential growth in size, which results in network congestion and server overloading. Web caching has been recognized as one of the effective schemes to alleviate the service bottleneck and reduce the network traffic, thereby minimize the user access latency. In this paper, we propose a Scalable Efficient Robust Adaptive (SERA) Web caching architecture which accommodates the exponential growth and extreme dynamic environment of the World Wide Web. We developed a piggybacked prefetching/ pre-resolving scheme, which uses user access pattern and network environment information. Cooperative consistency control mechanism is employed to further improve the performance. In order to assist the cache resolution, an efficient cache routing scheme is employed. A loose group membership is maintained among nearby proxy caches to make the entire caching system scalable and fault tolerant.

title: Formalization of Isabelle Meta Logic in NuPRL
abstract: NuPRL and Isabelle are two general purpose theorem provers. Both of them are based on a version

of Constructive Higher Order Type Theory. In an earlier work the author has proposed an informal semantics of Isabelle Meta Logic in an extension of NuPRL Type Theory. An automated converter, based on this semantics, has been developed, that translates Isabelle theorem statements into NuPRL. This work presents a formalization of the above semantics in NuPRL. It starts with a deep embedding of Isabelle type and term syntax into NuPRL Constructive Type Theory. Next, two internal NuPRL functions are defined. One of them maps Isabelle types into NuPRL types and the other maps Isabelle terms into elements of appropriate NuPRL types. These two functions provide an interpretation of Isabelle in NuPRL. Finally, interpretations of all Isabelle Meta Logic rules are proven as theorems in some classical extension of NuPRL Type Theory. This formalization is aimed to provide a more secure foundation for the interaction between two systems.

title: Tiling Imperfectly-nested Loops
abstract: Tiling is one of the more important transformations for enhancing locality of reference in programs. Intuitively, tiling a set of loops achieves the effect of interleaving iterations of these loops. Tiling has been applied only to perfectly-nested loop nests which are loop nests in which all assignment statements are contained in the innermost loop. In practice, most loop nests are imperfectly-nested, so existing techniques have limited utility. In this paper, we propose an approach to tiling imperfectly-nested loop nests. The key idea is to embed the iteration space of every statement in the imperfectly-nested loop nest into a special space called the product space which is tiled to produce the final code. We evaluate the effectiveness of this approach for dense numerical linear algebra benchmarks, relaxation codes, and the tomcatv code from the SPEC benchmarks. No other approach in the literature can tile all these codes automatically.

title: Securing Ad Hoc Networks
abstract: Ad hoc networks are a new wireless networking paradigm for mobile hosts. Unlike traditional mobile wireless networks, ad hoc networks do not rely on any fixed infrastructure. Instead, hosts rely on each other to keep the network connected. The military tactical and other security-sensitive operations are still the main applications of ad hoc networks, although there is a trend to adopt ad hoc networks for commercial uses due to their unique properties. One main challenge in design of these networks is their vulnerability to security attacks. In this paper, we study the threats an ad hoc network faces and the security goals to be achieved. We identify the new challenges and opportunities posed by this new networking environment and explore new approaches to secure its communication. In particular, we take advantage of the inherent redundancy in ad hoc networks --- multiple routes between nodes --- to defend routing against denial of

service attacks. We also use replication and new cryptographic schemes, such as threshold cryptography, to build a highly secure and highly available key management service, which forms the core of our security framework.

title: Alias Types
abstract: Linear type systems allow destructive operations such as object deallocation and imperative updates of functional data structures. These operations and others, such as the ability to reuse memory at different types, are essential in low-level typed languages. However, traditional linear type systems are too restrictive for use in low-level code where it is necessary to exploit pointer aliasing. We present a new typed language that allows functions to specify the shape of the store that they expect and to track the flow of pointers through a computation. Our type system is expressive enough to represent pointer aliasing and yet safely permit destructive operations.

title: The Horus and Ensemble Projects: Accomplishments and Limitations
abstract: The Horus and Ensemble efforts culminated a multi-year Cornell research program in process group communication used for fault-tolerance, security and adaptation. Our intent was to understand the degree to which a single system could offer flexibility and yet maintain high performance, to explore the integration of fault-tolerance with security and real-time mechanisms, and to increase trustworthiness of our solutions by applying formal methods. Here, we summarize the accomplishments of the effort and evaluate the successes and failures of the approach.

title: Query Processing in a Device Database System
abstract: In the next decade, networks of devices will be widely deployed for measurement, detection and surveillance applications. Millions of sensors and small-scale mobile devices will integrate processors, memory and communication capabilities. Large collections of devices need to be controlled and accessed in an ad-hoc manner. This paper shows that database technology can be adapted to meet the challenges of this new computing environment. In our new concept of a device database system, individual devices are modeled as database objects, which allows us to access collections of devices with declarative queries. We present a semantics for queries over device database systems and novel query processing techniques for evaluating such queries. We describe our implementation of these techniques in the Cornell COUGAR system and present a experimental evaluation that illustrates the performance characteristics of query processing in a device database system.

title: The Small-World Phenomenon: An Algorithmic Perspective
abstract: Long a matter of folklore, the ``small-world phenomenon'' --- the principle that we are all linked by short chains of acquaintances --- was inaugurated as an area of experimental study in the social sciences through the pioneering work of Stanley Milgram in the 1960's. This work was among the first to make the phenomenon quantitative, allowing people to speak of the ``six degrees of separation'' between any two people in the United States. Since then, a number of network models have been proposed as frameworks in which to study the problem analytically. One of the most refined of these models was formulated in recent work of Watts and Strogatz; their framework provided compelling evidence that the small-world phenomenon is pervasive in a range of networks arising in nature and technology, and a fundamental ingredient in the evolution of the World Wide Web. But existing models are insufficient to explain the striking algorithmic component of Milgram's original findings: that individuals using local information are collectively very effective at actually constructing short paths between two points in a social network. Although recently proposed network models are rich in short paths, we prove that no decentralized algorithm, operating with local information only, can construct short paths in these networks with non-negligible probability. We then define an infinite family of network models that naturally generalizes the Watts-Strogatz model, and show that for one of these models, there is a decentralized algorithm capable of finding short paths with high probability. More generally, we provide a strong characterization of this family of network models, showing that there is in fact a unique model within the family for which decentralized algorithms are effective.

title: The Next Generation Internet: Unsafe at Any Speed?
abstract: Will the Next Generation Internet provide an appropriate infrastructure for critical applications, such as are emerging in such settings as health care, electric power grid control, air traffic control, banking, and military command and control? This paper suggests that current trends are unlikely to yield the required platform. Drawing lessons from successful critical networking projects of the past, we propose an alternative based on Virtual Overlay Networks (VONs). Support for VONs would not require radical departure from existing router capabilities, because a limited mechanism of the type we propose is already available. Given a simple Overlay Network (ON) capability, we show that tools for building more sophisticated VONs are already widely available.

title: Efficient Reconciliation of Unordered Databases
abstract: We consider the problem of reconciling two unordered databases whose contents are related. Specifically, we wish to determine the mutual difference of these databases with a minimum communication complexity. This type of problem arises naturally in the context of gossip protocols. We analyze two instances of the reconciliation problem, a client-server model and a more general peer-to-peer model, and provide interactive solutions for both. For the former instance, we also provide a simple one-message reconciliation algorithm, based on elementary symmetric polynomials, which has an almost optimal communication complexity.

title: On Log-Tape Isomorphisms of Complete Sets
abstract: In this paper we study $\log n$-tape computable reductions between sets and investigate conditions under which $\log n$-tape reductions between sets can be extended to $\log n$-tape computable isomorphisms of these sets. As an application of these results we obtain easy to check necessary and sufficient conditions that sets complete under $\log n$-tape reductions in NL, CSL, P, NP, PTAPE, etc. are $\log n$-tape isomorphic to the previously known complete sets in the respective classes. As a matter of fact, all the "known" complete sets for NL, CSL, P, NP, PTAPE, etc. are now easily seen to be, respectively, $\log n$-tape isomorphic. These results strengthen and extend substantially the previously known results about polynomial time computable reductions and isomorphisms of NP and PTAPE complete sets. Furthermore, we show that any set complete in CSL, PTAPE, etc. must be dense and therefore, for example, cannot be over a single letter alphabet.

title: Analyzing and Improving Quasi-Newton Methods for Unconstrained Optimization
abstract: This thesis is concerned with analyzing and improving the performance of quasi-Newton methods for finding the minimum of a real valuedd function of a finite number of real variables. Quasi-Newton methods are a successful way of iteratively solving this problem when the Hessian matrix of second partial derivatives of the function cannot be cheaply computed. Instead they keep an approximation to the Hessian matrix at the current point, and update it at each iteration. A recent algorithm of Davidon's has contributed two important new ideas to the formulation of such updates, while improving upon the computational performance of existing algorithms. In this thesis we analyze the work of Davidon, propose some changes to his algorithm and test some of these, and extend much of the existing analysis of quasi-Newton updates for optimization problems to a broader class of updates which includes Davidon's. The two innovations in Davidon's algorithm are the use of a new update class intended to preserve past derivative information in the Hessian approximation, and the selection of the actual update from this class by a method called optimal conditioning. We explain and analyze both of these aspects thoroughly. The use of the new update class seems to be very beneficial, although our analysis suggests several alternative implementations which are

equivalent to Davidon's algorithm on quadratic problems. We extend existing convergence techniques to show that two of these methods enjoy local Q-superlinear convergence under normal assumptions. On the other hand, our theoretical and computational analysis of optimal conditioning indicates that it may not be helpful in most cases, and that further computational testing definitely is required. However, we introduce and test an update which uses optimal conditioning only on some selected iterations, and which seems to show promise. To aid our analysis of Davidon's ideas we introduce the concept of a restricted update class, of which his is an example. We then extend much of the existing analysis of rank-two quasi-Newton updates, including questions of hereditary positive definiteness, mimimum change updates, and performance using perfect line search, to include this broadened update class. This work helps suggest some of our proposed changes to Davidon's algorithm, and is useful in deriving and analyzing quasi-Newton updates for other problems. A basic equivalence shows that our analysis extends to a very general class of rank-two updates. Quasi-Newton methods are currently being applied in a variety of problem areas. We hope that our analysis improves upon their use in unconstrained optimization, and helps make the leading new ideas in the field accessible to other application areas.

title: An Adaptive Nonlinear Least-Squares Algorithm
abstract: NL2SOL is a modular program for solving nonlinear least-squares problems that incorporate a number of novel features. It maintains a secant approximation S to the second-order part of the least-squares Hessian and adaptively decides when to use this approximation. S is "sized" before updating, something which is similar to Oren-Luenberger scaling. The step choice algorithm is based on minimizing a local quadratic model of the sum of squares function constrained to an elliptical trust region centered at the current approximate minimizer. This is accomplished using ideas discussed by More', together with a special module for assessing the quality of the step thus computed. These and other ideas behind NL2SOL are discussed and its evolution and current implemetation are also described briefly.

title: Variable Metric Methods for Minimizing a Class of Nondifferentiable Functions
abstract: We develop a class of methods for minimizing a nondifferentiable function which is the maximum of a finite number of smooth functions. The methods proceed by solving iteratively qquadratic programming problems to generate search directions. For efficiency the matrices in the quadratic programming problems are suggested to be updated in a variable metric way. By doing so, the methods possess many attractive features of variable metric methods and can be viewed as their natural extension to the nondifferentiable case. To avoid the difficulties of an exact line search, a practical stepsize procedure is also introduced. Under mild asumptions the resulting method converge globally.

title: Local and Linear Convergence of an Algorithm for Solving A Sparse Minimization Problem
abstract: For an unconstrained minimization problem with a sparse Hessian, a symmetric version of Schubert's update is given which preserves the sparseness structure defined by the Hessian. At each iteration of the algorithm there are two sparse linear systems to be solved. These have the same sparseness structure defined by the Hessian. The differences between succeeding approximations to the Hessian and the Hessian at the solution are related by a careful evaluation of the difference in the Frobenius norm. This relation is used in proving the local and linear convergence of the algorithm.

title: Access Control in Parallel Programs
abstract: An important component of a programming language for writing operating systems, or other large parallel systems, is the set of access control facilities. Two principles for access control, expressive power and access validation, are discussed. Then two new language mechanisms are presented: one for expressing the static structure and access rights of parallel systems, the other for controlling dynamic access to shared objects (monitors). The use of the proposed mechanisms is illustrated by message passing and file systems. Finally, the relationship between the mechanisms and access validation is discussed and a solution to the safety problem for the facilities is given. Key Words and Phrases: access control, programming language,

protection, security, processes, monitors, access safety. CR Categories: 4.20, 4.32, 4.35

title: Mathematics and Information Retrieval
abstract: The development of a given discipline in science and technology often depends on the availability of theories capable of describing the processes which control the field and of modelling the interactions between these processes. The absence of an accepted theory of information retrieval has been blamed for the relative disorder and the lack of technical advances in the area. The main mathematical approaches to information retrieval are examined in this study, including both algebraic and probabilistic models, and the difficulties which impede the formalization of information retrieval processes are described. A number of developments are covered where new theoretical understandings have directly led to the improvement of retrieval techniques and operations.

title: Exploiting Sparsity in Newtown-Like Methods
abstract: The basic problem considered here is to solve sparse systems of nonlinear equations. A system is considered to be sparse when the Jacobian has fewer than ten percent nonzero entries. Algorithms are presented and their convergence properties are analyzed. Schubert's method for solving sparse nonlinear equations is a modification of Broyden's method, a well known quasi-Newton method. The modification preserves the zero-nonzero structure defined by the sparse Jacobian in the sequence of approximate Jacobians. The algorithm is shown to satisfy the Bounded Deterioration Theorem of Broyden, Dennis and More to obtain a simple local convergence result. A more detailed study of the error bound in the Frobenfus norm shows that the method is superlinearly convergent. Schubert's method satisfies a minimum norm property and a Kantorovich analysis is also presented. A symmetric Schubert update is derived using an iterative projection technique of Dennis and Powell. The update is expressed in a closed form at the expense of an additional sparse linear system to be solved at each iteration in the algorithm. These sparse linear systems that occur all have the same structure which means they can be handled using the pre-processing performed when solving the first such system. Again the Frobenfus norm is used to estimate the error in the approximate Jacobian. The algorithm is locally and linearly convergent. The update is applicable to a symmetric nonlinear system, particularly those systems arising from unconstrained minimization problems with a continuous second derivative. Another method of solving sparse nonlinear equations using a matrix factorization is presented. Some theory of sparse linear equations is needed to maintain sparseness in triangular factors of a matrix. An approximate Jacobian is factored and one of the triangular factors is updated with Schubert's updating formula. After a finite number of iterations, a new approximate Jacobian is needed. Algorithms are suggested with local and superlinear convergence properties. The convergence depends on the local continuity of the matrix factorization. Finally, another application of Schubert's method is proposed for problems in which the Jacobian of the nonlinear system can be written as the direct sum of two transformations. One of these is assumed to be easily computed, and the other is assumed to be sparse. An algorithm is sketched and local and superlinear convergence properties are conjectured.

title: Superlinear Convergence of a Minimax Method
abstract: To solve a minimax problem Han [1977b] suggested the use of quadratic programs to find search

directions. If the matrices in the quadratic programs are positive definite, the method can be shown convergent globally. In this paper we study that for efficiency the matrices should also be good approximations to a certain convex combination of Hessians on some subspace. Therefore, we suggest Powell's scheme [Powell 1977] for updating these matrices. By doing so, we can avoid computing Hessians. Meanwhile, the matrices maintain positive definiteness and Han's global convergence theorems can apply. Besides, the convergence of the resulting method is superlinear, indeed.

title: Least Change Secant Updates for Quasi-Newton Methods
abstract: In many problems involving the solution of a system of nonlinear equations, it is necessary to keep an approximation to the Jacobian matrix which is updated at each iteration. Computational experience indicates that the best updates are those that minimize some reasonable measure of the change to the current Jacobian approximation subject to the new approximation obeying a secant condition and perhaps some other approximation properties such as symmetry. In this paper we extend the affine case of a theorem of Cheney and Goldstein on proximity maps of convex sets to show that a generalization of the symmetrization technique of Powell always generates least change updates. This generalization has such broad applicability that we obtain an easy unified derivation of all the most successful updates. Furthermore, our techniques apply to interesting new cases such as when the secant condition might be inconsistent with some essential approximation property like sparsity. We also offer advice on how to choose the properties which are to be incorporated into the approximations and how to choose the measure of changes to be minimized.

title: One-Way Log-Tape Reductions
abstract: One-way log-tape (1-L) reductions are mappings defined by log-tape Turing machines whose read head on the input can only move to the right. The 1-L reductions provide a more refined tool for studying the feasible complexity classes than the P-time [2,7] or log-tape [4] reductions. Although the 1-L computations are provably weaker than the feasible classes L, NL, P and NP, the known complete sets for those classes are complete under 1-L reductions. However, using known techniques of counting arguments and recursion theory we show that certain log-tape reductions cannot be 1-L and we construct sets that are complete under log-tape reductions but not under 1-L reductions.

title: An Improved Simulation Result for Ink Bounded Turing Machines
abstract: A (one tape, deterministic) Turing machine is $f(n)$ ink bounded if the machine changes a symbol of its work tape at most $O(f(n))$ times while processing any input of length n. The main result of our paper is the construction of an "ink efficient" universal machine which, for any $f(n)$ ink bounded machine M and input x, can simulate the processing of M on x or detect that M is looping infinitely on input x. The universal machine requires $O(f(n)^{1+\epsilon})$ ink for this simulation where ϵ is an arbitrarily small positive number. As a corollary, we establish that the class of all $f(n)$ ink bounded computations is properly contained in the class of all $g(n)$ ink bounded computations assuming $\stackrel{inf}{n \rightarrow \infty} \frac{f(n)^{1+\varepsilon}}{g(n)} = 0$ and a technical condition on g.

title: Information Flow in Parallel Programs: An Axiomatic Approach
abstract: The information flow problem is concerned with controlling the transmission of information in computer systems. This thesis addresses this problem by developing an axiomatic logic that captures the information flow semantics of a program. Using this technique the scope of information flow analysis is extended from terminating sequential programs to parallel programs in which non-termination, synchronization and deadlock are possible. Once the information flow generated by a program has been determined, it is easy to check whether or not the program satisfies a given security policy. The main contribution of the thesis is an axiomatic proof system for determining the flow of information produced

by sequential or parallel programs. Just as proofs of correctness capture the effect of program execution upon the values in variables, proofs of information flow capture the effect of program execution upon the information in variables. An advantage of this approach is that once a flow proof of a program has been generated, various security policies, such as high water mark or final value, can be verified readily. Although flows in parallel programs need to be determined so that confidentiality in shared systems can be maintained, current information flow techniques are limited to terminating sequential programs. The thesis addresses this problem by capturing the flows generated by programs containing independent processes that synchronize with each other. The practicability of the method is demonstrated by developing the flow semantics for Concurrent Pascal.

title: An Efficient Algorithm for Testing Losslessness of Joins in Relational Data Bases
abstract: Answering queries in a relational database model often requires the computation of joins of relations. Losslessness of joins is an important property for joins of relations to be semantically meaningful. In this paper we present an $O(n^{3})$ algorithm for testing losslessness of joins in relational databases with functional dependencies, which improves the $O(n^{4})$ result by Aho, Beeri and Ullman.

title: A Note on the Evaluation of Matrix Polynomials
abstract: The problem of evaluating a polynomial p(x) in a matrix A arises in many applications, e.g. the Taylor approximation of e^{A}. The $O(\sqrt{q}n^{3})$ algorithm of Paterson and Stockmeyer has the drawback that it requires $O(\sqrt{q}n^{2})$ storage, where q is the degree of p and n is the dimension of A. An algorithm which greatly reduces this storage requirement without undue loss of speed is presented.

title: A Hessenberg-Schur Method for the Problem AX + XB = C
abstract: One of the most effective methods for solving the matrix equation AX + XB = C is the Bartels-Stewart algorithm. Key to this technique is the orthogonal reduction of A and B to triangular form using the QR algorithm for eigenvalues. A new method is proposed which differs from the Bartels-Stewart algorithm in that A is only reduced to Hessenberg form. The resulting algorithm is between 30 and 70 percent faster

depending upon the dimensions of the matrices A and B. The stability of the new method is demonstrated through a roundoff error analysis and supported by numerical tests. Fianlly, it is shown how the techniques described can be applied and generalized to other matrix equation problems.

title: Classes and Objects - A Dynamic Approach
abstract: Data encapsulation, abstract data types and classes are terms associated with a concept not fully clarified or accepted. This paper presents a class concept that differs slightly from previous definitions by the associated dynamics. This allows us to interpret nested and recursive classes as well as class parameters. We will distinguish between types and classes and permit types as parameters in a way that allows simple implementation. A number of examples will be given to illustrate the class concept itself and its application to access control problems for concurrent programs. Synchronization primitives will be viewed as classes and the need for explicit high-level constructs like monitors is questioned. Keywords: Programming language, encapsulation, abstract data type, class, object, synchronization, monitor.

title: Sorting and Searching Using Controlled Density Arrays
abstract: Algorithms like insertion sort run slowly because of costly shifting of array elements when a value is inserted or deleted. The amount of shifting, however, can be reduced by leaving gaps - unused array locations into which new values can be inserted - at regular intervals in the array. The proper arrangement of gaps is maintained by periodic adjustment. We demonstrate this technique with a stable comparison sort algorithm with expected time $O(N \log N)$, worst case time $O(N \sqrt{N})$, and space requirements 2N. We conjecture that, by using an interpolation search, the expected time can be reduced to $O(N \log \log N)$. By comparison, Quicksort takes expected time $O(N \log N)$, worst case time $O(N^{2})$ and space $N + \log N$. Second, we show that for any fixed $d \geq 2$ a table management algorithm can be constructed that can process a sequence of N instructions chosen from among INSERT, DELETE, SEARCH, and, MIN in worst case time $O(N^{1+1/d})$. Experiments with a version of the algorithms using $d=2$ show a marked improvement over balanced tree schemes for N as large as several thousand.

title: Efficiency Considerations In Implementing Dijkstra's Guarded Command Constructs
abstract: The guarded command alternative and iterative constructs proposed by E. W. Dijkstra subsume the conventional alternative and iterative constructs. The extra flexibility of these guarded command constructs enables the programmer to express his ideas more directly and clearly. Moreover, Dijkstra has developed a calculus for the derivation of correct programs that utilizes these guarded command constructs. This thesis addresses the problem of efficiently implementing these guarded command constructs. Several new optimizations that are particularly well suited to the guarded command constructs are described. The most useful is the elimination of redundant boolean expressions. This optimization provides a means of implementing the guarded command alternative statement with efficiency comparable to the IF-THEN-ELSE statement. The main contribution of this thesis is a detailed description of an algorithm for eliminating redundant boolean expressions. The algorithm itself is presented in a program written in a PASCAL supplemented with the guarded command constructs. The basis method involves considering individual execution paths through the guarded command construct and applying rules of inference to recognize and avoid evaluation of many boolean expressions. It is shown that the number of execution paths through a guarded command construct remains small enough to make this method practical.

title: Local Convergence Theorems for Quasi-Newton Methods
abstract: This paper presents generalizations of the two results which have been useful for analyzing methods of the form $x_{k+1} = x_{k} - B_{k}^{-1}F(x_{k})$. The bounded deterioration theorem of Broyden-Dennis-More is generalized to show that if \{B_{k}\} or \{B_{k}^{-1}\} is of bounded deterioration as a sequence

of approximants to some B_{*} or B_{*}^{-1} then the iteration above has the same local convergence properties and arbitrarily nearly the same linear rate as would be achieved by the stationary iteration function which uses $B_{k} = B_{*}$. The characterization theorem for superlinear convergence given by Dennis-More is then generalized to give conditions under which the rates are the same. In the case when $B_{*} = F'(x_{*})$, these results reduce to those already known.

title: The Complexity of Parallel Computations
abstract: Recent advances in microelectronics have brought closer to feasibility the construction of computers containing thousands (or more) of processing elements. This thesis addresses the question of effective utilization of such processing power. We study the computational complexity of synchronous paarallel computations using a model of computation based on random access machines operating in parallel and sharing a common memory, the P-RAM. Two main areas within the field of parallel computational complexity are investigated. First, we explore the power of the P-RAM model viewed as an abstract computing device. Later, we study techniques for developing efficient algorithms for parallel computers. We are able

to give concise characterizations of the power of deterministic and nondeterministic P-RAMS in terms of the more widely known space and time complexity classes for multi-tape Turing machines. Roughly speaking, time-bounded deterministic P-RAMS are equivalent in power to (can accept the same sets as) space-bounded Turing machines, where the time and space bounds differ by at most a polynomial. In the context of comparing models of computation, we consider such polynomial differences in resources to be insignificant. Adding the feature of nondeterminism to the time-bounded P-RAM changes its power to that of a nondeterministic Turing machine with an exponentially higher running time. The later sections of the thesis examine algorithm design techniques for parallel computers. We first develop efficient procedures for some common operations on linked lists and arrays. Given this background, we introduce three techniques that permit the design of parallel algorithms that are efficient in terms of both their time and processor requirements. We illustrate the use of these techniques by presenting time and processor efficient algorithms for three problems, in each case improving upon the best previously known parallel resource bounds. We show how to compute minimum string edit distances, using the technique of pairwise function composition. We describe an algorithm for the off-line MIN that organizes its computation in the form of a complete binary tree. Finally, we present an algorithm for undirected graph connectivity that relies on redundancy in its representation of the input graph.

title: On Easily Infinite Sets and On a Statement of R. Lipton
abstract: For a complexity measure κ, a set is κ-infinite if it contains a κ-decidable infinite subset. For a time-based κ, we prove that there is a recursive S s.t. both S and its complements, $\bar{S}$, are infinite but not κ-infinite. Lipton [6] states that the existence of a recursive set S s.t. neither S nor $\bar{S}$ os polynomially infinite is not a purely logical consequence of $\prod^{0}_{2}$ theorems of Peano's Arithmetic PA. His proof uses a construction of an algorithm within a non-standard model of of Arithmetic, in which the existence of infinite descending chains in such models is overlooked. We give a proof of a stronger statement to the effect that the existence of a recursive set S s.t. neither S nor $\bar{S}$ is linearly infinite is not a tautological consequence of all true $\prod^{0}_{2}$ assertions. We comment on other aspects of [6], and show $(\S 2)$ that a tautological consequence of true $\prod^{0}_{2}$ assertions may not be equivalent (in PA, say) to a $\prod^{0}_{2}$ sentence. The three sections of this paper use techniques of Recursion Theory, Proof Theory and Model Theory, respectively.

title: Quadratic Programming with M-Matrices
abstract: In this paper, we study the problem of quadratic programming with M-matrices. We describe (1) an effective algorithm for the case where the variables are subject to a lower bound constraint, and (2) an

analogous algorithm for the case where the variables are subject to lower and upper bounds constraints. We demonstrate the special monotone behavior of the iterate and gradient vectors. The result on the gradient vector is new. It leads us to consider a simple updating procedure which preserves the monotonicity of both vectors. The procedure uses the fact that an M-matrix has a non-negative inverse. Two new algorithms are then constructed by incorporating this updating procedure into the two given algorithms. We give numerical examples which show that the new methods can be more efficient than the original ones.

title: On the Modelling Power of Petri Nets
abstract: The behavior of a Petri net is expressed as a formal language. Certain families of Petri net languages are characterized by propositions similar to the classical pumping theorems. The results are used to give examples of behaviors that cannot be expressed by languages in these families.

title: Data Curation and Distribution in Support of Cornell University's Upper Susquehanna Agricultural Ecology Program
abstract: Paper presented at DigCCurr2007, an international symposium on Digital Curation. Held April 18-20, 2007 at the University of North Carolina, Chapel Hill NC.Effective documentation, curation, and provision of access to scientific data are essential to derive the full benefit of research data, both for participants in specific research projects and for the entire scientific community. Academic research libraries are positioned to be important partners in such endeavors, although success will depend in part on expanding and changing the customary roles of, and relationships between, researchers and libraries. Cornell University's Albert R. Mann Library is collaborating with the Upper Susquehanna Agricultural Ecology Program at Cornell to document and distribute the group's research data. In addition to collecting data and developing numeric and spatial models, the research group has access to approximately thirty years worth of observational data for their research sites, which are of significant value to environmental scientists. The approach includes identifying and using discipline-specific metadata standards in order to facilitate participation in discipline-specific data and metadata sharing initiatives, at the discretion of individual researchers. Training is provided for project collaborators in the use of existing metadata creation tools to create documentation for their datasets. ?Pre-publication? data and metadata are stored in a database accessible only by project members, to facilitate early sharing and collaboration within the group. Complete, documented data sets and complete metadata records will then be deposited in Cornell's DSpace installation. As a test case, the historic data sets are being formatted and documented for deposit in DSpace. A public web portal provides information about the project and participants, as well as a future means of access to project datasets.National Science Foundation grant number 0437603 to Janet McCue and Barbara Lust

title: Textural Ambiguity In The Piano Music Of Johannes Brahms
abstract: This dissertation examines textural ambiguity in the piano music of Johannes Brahms and contextualizes this aspect of his compositional style with discussions of nineteenth-century performance practice, and changes in piano building during Brahms?s life. Recent analyses of Brahms?s music have emphasized several types of ambiguity encountered, including metrical, harmonic, and formal ambiguity. This dissertation focuses on Brahms?s use of textural ambiguity: specifically, his frequent obscuring of

thematic lines, obscuring the identity of individual lines in polyphonic works, and fluctuating hierarchies among individual voices. The question of balance and melodic clarity has been a primary concern for scholars concerned with historically-informed performance of Brahms?s music. However, many of these scholars have misinterpreted Brahms?s piano-writing, and misconstrued historical evidence as to Brahms?s preferences regarding instrument. This dissertation proposes new ways of understanding the relationship between Brahms?s music and changes in piano building based on analysis of his textures, and a consideration of late-ninteenth-century treatises on performance and composition.

title: Fate and Transport Modeling of Pesticides Applied to Turf
abstract: This research centers on modeling fate and transport processes affecting pesticides applied to turfgrass systems. Interest in predicting pesticide fate and transport from these systems stems from observations of pesticide residues in urban surface and groundwaters, and the need for information with which to assess human health and ecological risks of using these pesticides, total maximum daily load and other water quality management studies. The main processes that affect pesticide fate and transport in turf systems are reviewed, and general magnitudes of each process are reported. Dissipation rates for turf systems are compared to half-life values for aerobic decay in soil, photolysis and field dissipation. From this analysis, microbial decay appears to be a major factor in pesticide dissipation. Decay rates specific for turf are developed based on dissipation rates from these systems. The hypothesis that the use of soil-based decay rates leads to overestimation of pesticide runoff, volatilization and leaching losses from turfgrass systems is tested by means of long term simulations involving diverse turf, climatic and management conditions. Results indicate significant differences in estimations based on soil and turf decay rates as a result of differences in estimating the pesticide's persistence in the turf foliage and thatch. However, care should be taken when modeling pesticides that are weakly sorbed to organic matter. The research also includes the development of a volatilization model that is based on splitting pesticides into surface and retained deposits and allowing volatilization to occur from the surface deposits only. This model replicated daily volatilization fluxes better than models previously developed for turf, and was incorporated into the Turf Pesticide Model (TPM), which was designed to predict pesticide runoff, leaching, volatilization and decay on a daily basis using relatively few input parameters. Uncalibrated tests of TPM against data from diverse field studies indicated that the model explained 75% of the observed variation in drainage, 63% for pesticide leaching, 65% for runoff volumes, 64% for pesticide loss in runoff, and 62% for pesticide volatilization. TPM can provide information for risk, TMDL, environmental and water quality studies centered on evaluating the impacts of pesticides applied to turf.

title: A Defense of Non-reductive Physicalism
abstract: I develop a novel formulation of, and argument for, non-reductive physicalism - roughly, the view that mental properties are natural properties that are realized by, but not identical to, neural and other low-level physical properties. Non-reductive physicalism has long been the dominant view in the philosophy of mind but has recently been challenged from two main directions. The first type of attack, the causal exclusion problem, points out an apparent inconsistency in non-reductive physicalism. The second type of attack focuses on the multiple realizability of mental properties: questioning either its prevalence or its

efficacy in blocking reduction.
In response to the exclusion problem, I first argue that one of the claims used to formulate the problem, the completeness of physics, has two parts and that there is no single domain of physical entities that is the smallest domain of which both parts are true. The conflation of these two parts has made it appear that non-reductive physicalism is inconsistent. I then show how to use the two completeness claims as part of an argument for a form of physicalism that need not be reductive.
In response to the second type of attack, I provide a novel basis for the irreducibility of mental properties. I argue that irreducibility is ultimately grounded in relations between mechanisms, of which multiple realizability is merely one facet. The other facet, multiple determinativity - in which a single physical property realizes several different kinds of high-level properties - is equally effective at blocking property reduction. Thus, even if the doubts about the multiple realizability of mental properties (and its efficacy in blocking reduction) were sound, this would not undermine non-reductive physicalism. Another virtue of this framework is that it provides an adequate metaphysical basis for some of non-reductive physicalism's explanatory claims - e.g., that high-level explanations are sometimes deeper and theoretically more fecund than low-level physical explanations.Andrew W. title: Unveiling Christian Motifs in Select Writers of Harlem Renaissance Literature
abstract: Prior to the early 1900s, much of the artistic expression of African American writers and artists was strongly steeped in a Christian tradition. With the Harlem Renaissance (roughly 1917-1934), the paradigm shifted to some degree.
An examination of several books and articles written during and about the Harlem Renaissance revealed that very few emphasized religion as a major theme of influence on Renaissance artists. This would suggest that African American intelligentsia in the first three decades of the twentieth century were free of the strong ties to church and Christianity that had been a lifeline to so many for so long. However, this writer suggests that, as part of an African American community deeply rooted in Christianity, writers and artists of the Harlem Renaissance period must have had some roots in and expression of that same experience.
The major focus of this research, therefore, is to discover and document the extent to which Christianity influenced the Harlem Renaissance. The research is intended to answer the following questions concerning the relationship of Christianity to the Harlem Renaissance:
1. What was the historical and religious context of the Harlem Renaissance?
2. To what extent did Christianity influence the writers and artists of the Harlem Renaissance?
3. Did the tone of their artistry change greatly from the previous century? If so, what were the catalysts?
4. Three notable pre-twentieth-century African American writers apparently had been able to come to terms with Christianity. Were the Renaissance artists able to do it? Why or why not?
5. What made their views different?
6. What personal experiences did the Renaissance artists have with Christianity?
7. How was this Christian influence manifested in the literature? Methods used to accomplish this discovery will include library research covering historical studies of Christianity and literature in the African American community from the 1700s into the 1930s, autobiographical and biographical research of the Harlem Renaissance artists, and an analysis of selected works, concentrating on the poetry. The study will include a look at Christianity in the African American community at large, as well as other factors. Intellectual and literary pursuits during the early decades of the twentieth century were paralleled by growth and diversity in the African American church. It is the consciousness that gave impetus to both these movements that this

writer will explore. This portion of the paper will address the views of important early twentieth century figures as well as factors that influenced the urban religious landscape. The next portion of the paper will highlight the individual Christian background and experiences of some of the artists with whose works the Renaissance is most closely identified. This study will address the artists? own perspectives, as told in their autobiographies and biographies. This study will include an overview of the works of select writers of the Harlem Renaissance period and provide an analysis of works relevant to this thesis. The discussion will focus on the underlying expression of certain themes derived from Christian Scripture, including the following:
God?s relation to humans?Jesus as Savior, deliverer, judge, source of hope
Theme of equality (one God, one blood, one Spirit; no respect of persons)
Celebration of African beauty/self as created by God and made in His image
Christianity interwoven in the fabric of everyday life.
This portion of the paper also will address the works of some artists who, rather than embracing Christianity, may have used it in their works as a point of departure, highlighting its challenges and shortcomings.

title: Isoperimetric Constants and Self-Avoiding Walks and Polygons on Hyperbolic Coxeter Groups
abstract: Kenneth Brown, Laurent Saloff-Coste, David HendersonWe study isoperimetric constants of and self-avoiding walks (SAWs) and self-avoiding polygons (SAPs) on Cayley graphs of hyperbolic Coxeter groups. These graphs are tilings of the hyperbolic plane. We calculate the isoperimetric constants of most rank three hyperbolic Coxeter groups and give an estimate for the remainder. We prove that for all but a few classes of these groups there are exponentially fewer k-step SAPs than there are k-step SAWs. We prove that this is also true of any nontrivial free product. Additionally we show that there are exponentially more k-step SAWs on a free group F_n (resp. a ?free? Coxeter group T_d) than on any strict subgroup of F_n (resp. T_d).

title: A Boroscopic Quantitative Imaging Technique For Sheet Flow Measurements
abstract: A boroscopic imaging system is developed to measure sediment velocities within a highly concentrated sheet layer in open channel flows. A detailed literature review is presented to investigate previous attempts at sheet layer measurements, followed by a set of experiments to determine clean water flow characteristics in the open channel flume located in the DeFrees Hydraulics Laboratory. Experiments are carried out in the same flume under sediment-laden, sheet flow conditions to determine the steadiness of the flow as well as to verify velocities in the suspended sediment transport region with existing theories.
Sediment velocities are captured in the highly concentrated sediment sheet for the same flow conditions using the new boroscopic imaging system. The boroscope is a minimally intrusive lens with a diameter that is only an order of magnitude larger than the natural sand being studied. Minimum Quadratic Difference techniques, along with several filtering techniques, are utilized to determine particle displacements. A rigorous investigation into calibrations is included in order to convert pixel displacements into physical velocities. Three separate metrics are investigated, all involving light intensity values. These metrics are examined from calibrations performed under fixed, moving and in-situ experimental conditions. The limitation of each calibration as well as a discussion of the effectiveness of the calibration techniques is included.
Physical velocities within the sheet layer are determined using the in-situ variance of intensity calibration. A complete streamwise velocity profile spanning from the non-moving bed to the free stream is included

which combines velocity data collected from both the boroscopic imaging technique as well as an acoustic Doppler velocimeter. The joint profile seems fairly continuous but more attention needs to be focused on the velocities located along the interface of the sheet flow and suspended regions as well as possible reasons for differences between these experimental results and results published previously.
Finally, future development is discussed including the further investigation into calibration techniques, the possibility of measuring sediment concentrations as well as water velocities and other possible uses for the boroscopic quantitative imaging technique.

title: Youth-adult Partnerships Creating Positive Environmental Change
abstract: When youth create positive environmental change in their communities they typically act with adult guidance. The role of adults, however, is largely absent in literature around youth participation in environmental action. This research explored through phenomenological interviews with 33 practitioners (e.g., teachers, extension educators, community organizers) facilitating youth environmental action in formal and non-formal educational settings across the U.S.: (a) ways practitioners involved youth in environmental action, (b) purposes and goals motivating practitioners to engage youth in environmental action, and (c) methods practitioners used to facilitate youth environmental action. The study sought insight into successful and challenging experiences. It also inquired about the meaning of these experiences for participating youth through group interviews with 46 youth in 9 programs. Practice accounts included multiple forms of action among five types: physical improvements, community education, inquiry, advocacy, and contributions to community development. Practitioners described purposes integrating multiple individual, environmental, and community development goals. Most placed higher value in developing youth as citizens and change agents than in promoting environmental improvements. Evident in practitioners' narratives was a tension between encouraging youth autonomy while maintaining authority. Practitioners experienced and managed this 'autonomy-authority duality' differently but all described characteristics of youth-adult partnerships. Nine practice themes emerged: creating safe spaces; providing structure; building relationships; bridging differences; setting rigorous expectations; providing opportunities for meaningful contribution; supporting youth; expanding horizons; and connecting youth with community. Youth reported learning in physical (e.g., fitness), intellectual (e.g., technological skills), psychological (e.g., initiative), and social (e.g., teamwork) domains. Parallel themes with youth development literature suggest environmental action is a valuable context for positive youth development. The interplay of science education and community action evident in practitioner and youth interviews suggests the merit of a theoretical framework where environmental action occurs at the intersection of inquiry-based science education and youth civic engagement. Participation in environmental action enhanced some youths' capabilities in 'practical inquiry' and influenced some youths' perceptions of themselves from passive to active citizens. Environmental action concurrently involves youth in civic and scientific processes through which they can develop the critical dispositions and skills characteristic of both endeavors.Cornell University Agricultural Experiment Station federal formula funds, Project No. NYC-147459, received from the Cooperative State Research, Education and Extension Service, U.S. Department of Agriculture

title: Constrained Optimization in Human Running

abstract: Walking humans spontaneously select different speed, frequency, and step length combinations depending on which of these three parameters is specified. This behavior can be explained by constrained optimization of cost of transport (metabolic cost/distance) where cost of transport is seen as the main component of an underlying objective function that is minimized within the limitations of specified constraints. It is then of interest to ask whether or not such results are specific to walking only or indicate a more general feature of locomotion control. The current study examines running gait selection within the framework of constrained optimization by comparing self-selected running gaits to the gaits predicted by constrained optimization of a cost surface constructed from cost data available in the literature. Normalizing speed and frequency values in the behavioral data by preferred speed and frequency reduced inter-subject variability and made group behavioral trends more visible. Although actual behavior did not coincide exactly with running cost optimization, self-selected gait and predictions from the general human cost surface did agree to within the 95% confidence interval and the minimal cost + 0.005 mLO2/kg/m region. This was similar to the level of agreement between actual and predicted behavior observed in walking. Thus, there seems to be substantial evidence to suggest that 1) Selection of gait parameters in running can largely be predicted using constrained optimization and 2) General cost surfaces can be constructed using metabolic data from one group that will roughly predict the behavior of other groups.NSF

title: Coexistence of Contact Processes
abstract: Neuhauser (1992) considered the competition between two contact processes and showed that on $\Z^2$ coexistence is not possible if the death rates are equal and the particles use the same dispersal neighborhood. In this thesis we consider two variations of the competition model. In the first model a species with a long range dispersal kernel competes with a superior competitor with nearest neighbor dispersal. We show that the two species can coexist when we introduce blocks of deaths due to “forest fires”. In the second model particles with long range dispersals compete in an environment with two distinct seasons. Birth rate for each species is piecewise constant and periodic. We show that there is coexistence when the two species have distinct growing seasons.

title: National Subjects, International Selves: Feminist Self-fashioning in Meiji Japan and Nineteenth Century Colonial India
abstract: ?National Subjects, International Selves: Feminist Self-fashioning in Meiji Japan and Colonial India,? is a historical and literary-critical inquiry into the complex relationships that Asian women in the 19C forged across the North-South divide. I argue that when such women overstepped the bounds of nation to embrace a larger sisterhood, they placed themselves in an anomalous position with regard to the nation-state?as citizen-subjects and as feminists. In particular, I examine the work of Japanese feminist and educator Tsuda Umeko (1864-1929) in conjunction with that of the Indian feminist Pandita Ramabai (1858-1922) for both of whom an engagement with the task of female education and social reform at home became possible through the emotional and material support provided by their American counterparts. Reading Ramabai?s The High-caste Hindu Woman (1888) together with Japanese Girls and Women (1891) co-authored by Tsuda and her American friend Alice Bacon I focus on the logic of the triadic encounter between Tsuda, Ramabai and the American women who espoused their cause. I analyse these two texts in terms of the key paradox underlying

the Japanese understanding of their own Asianness: while they sought to identify with the ?civilised? West the Japanese at the same time could not but recognize cultural affinities with India and thereby ?Asia.? In the dissertation, my historical-semantic survey of the emergence of ?Asia? in the Japanese imaginary in this period is offset by an examination of 19C constructions of ?ideal? womanhood that sought to locate woman within the nation. Here I describe Tsuda?s uncomfortable relation to her country and its language because of her early life in America; I suggest that Tsuda?s commitment to the cause of international sisterhood had the paradoxical effect of making her acquiesce to the Meiji?s state?s project for a modern ?Japanese? woman. Finally, my examination of Tsuda?s voluminous correspondence with her American mother as framed in ?ba Minako?s biography and translation of these letters seeks to draw attention to the fact that both ?Asian? and ?Japanese? continued to be reinscribed in this period, most effectively through discourses extolling the so-called uniqueness of the Japanese language.

title: Role of Selected Fruits and Phytochemicals in Cancer Prevention: Mechanisms of Action
abstract: Epidemiological studies have shown that high consumption of fruits and vegetables is associated with reduced risk of cancer. Phytochemicals, mainly phenolics and flavonoids, have been suggested to be responsible for these health benefits. However, the molecular mechanisms of the anticancer effects of fruits and vegetables are not fully understood.
Fourteen grape varieties were analyzed for the profiles of total phenolics, total flavonoids, and trans-resveratrol. Phytochemicals in those grapes have potent antioxidant and antiproliferative activities. In addition, thirteen grape varieties and fourteen common phytochemicals were evaluated for their ability to induce mammalian phase II detoxification enzyme ? quinone reductase. Grape phytochemicals had strong activity in quinone reductase induction and potent antiproliferative activities toward Hepa1c1c7 cells. These results support the hypothesis that phytochemicals prevent cancer by acting as free radical scavengers and/or inducers of phase II detoxifying enzymes in the initiation stage, and/or as cell proliferation suppressors in the promotion/progression stages.
Combinations of selected fruits and phytochemicals were studied for their antioxidant activity, antiproliferative activity, and induction of quinone reductase. The combination of apple extracts and quercetin 3-b-D-glucoside (Q3G) exhibited more potent antiproliferative activity when compared to the apple extracts and Q3G alone. The combination of grape extracts and quercetin, genistein, and resveratrol showed higher induction activity of quinone reductase than grape extracts and phytochemicals alone.
In conclusion, we have demonstrated that the additive and synergistic effects of phytochemicals in fruits are responsible for their potent antioxidant activity, antiproliferative activity, and phase II detoxifying enzyme induction activity, and that the health benefit of a diet rich in fruits is attributed to the complex mixture of phytochemicals and their interactions present in those foods.

title: Some Results in Universal and A Priori Optimization
abstract: In this thesis, some combinatorial problems are studied in the light of the a priori and universal optimization framework, as introduced for the Traveling Salesman Problem by Jaillet, and by Bartholdi & Platzman, respectively. In both the a priori, as well as the universal framework, there is an underlying optimization problem, and (advance) knowledge of the potential instances that can arise. The goal is to

find a "master solution" of a special form, that in turn fully specifies the solution to any potential instance of the optimization problem that arises. In the case of the traveling salesman problem, the master solution is a tour on the complete set of all customers in the potential instances. This master tour now specifies the solution for each instance as follows: the customers in the instance will be visited in the same order as the master solution.
The results of this thesis include an optimization algorithm for the a priori and universal Traveling Salesman Problem on tree metrics, an $O(\log n)$-approximation algorithm for the a priori Traveling Salesman Problem, with no restrictions on the metric space and no knowledge about the probability distribution on the potential instances, an approximation algorithm for a priori and universal $1\,|\,pmtn, r_j\,|\,\sum C_j$, and a nearly optimal algorithm for AdWords.
We also study the real life problem of creating Nearly Isogenic Lines (NILs). The solution that we propose can be seen as an a priori solution, since the solution that we propose is nonadaptive. Finally, in addition to dealing with a priori and universal optimization, we also give a Fully Polynomial Time Approximation Scheme (FPTAS) for a certain Stochastic Dynamic Programs, with an application in option pricing.

title: Hybridizing Cellular and Behavioral Neurobiology with Modern Engineering Tools: Microelectronics, Microfabricated Devices, and Software Solutions for Physiology
abstract: Trained as an electrical engineer and physicist, I have learned the language of the modern neurobiologist and analyzed the state of experimental metrology (measurement tools) and laboratory based undergraduate education in the field (Neurobiology & Behavior). As a result of this examination, I develop solutions that offer a new kind of resolution and accessibility to physiological preparations from the sub-cellular to organismal level. My goal is to create an instrumentation toolset that trivializes the solutions to many of the current questions in neurophysiology and enable the experimenter to access higher resolution and new kinds of data about a system. My goal is to allow for new kinds of questions to be asked and answered. This represents the essence of mission of biophysics: Bringing the tools and methods of modern physics to revolutionize studies of biological systems.
I present three distinct projects which illustrate my findings. These projects bring the majority of modern electrical engineering tools and methods to focus on physiological questions in neural systems. The first project illustrates how a time critical microcontroller driven data acquisition and instrumentation system revolutionizes behavioral analysis in model organisms. The second projects brings the tools of the worlds foremost biophysical nanotechnology center (Cornell?s Nanobiotechnology Center, NBTC) to the design of a new kind of polymer substrate microelectrode structure capable of implantation and extracellular recording from sub-millimeter processes in intact animals. The third project describes a software data acquisition and analysis program capable of acquiring data and analyzing events in a variety of useful ways.
These projects should be viewed as responses to questions about the method, itself, of making observations and analysis in neurophysiological research and education environments. These projects describe tools that are currently being applied at a variety of institutions including several affiliates of Cornell to produce dramatic results. It is my goal to bring the experimental mind of yesterday?s behavioral and cellular neurobiologist into the realm of today?s biophysical engineering tools.

title: An Information-Theoretic Study of Cooperation in Networks
abstract: This thesis presents a study of cooperation in networks using the tools of information theory.
We first review the basic network models, with an emphasis on the relay channel, as this is the most basic configuration of cooperative communication. We focus on the estimate-and-forward (EAF) relaying strategy, which is a scheme that does not require the relay to decode the source messages. We investigate EAF with assignments of the auxiliary random variable that satisfy the feasibility constraint and present an alternative characterization of the classic EAF result of [Cover & El-Gamal, 1979] without a feasibility constraint, thus simplifying the description of the rate.
Next, we combine the relay channel with the broadcast channel. This combination is used to study communication over the general discrete memoryless broadcast channel (BC) with partially cooperating receivers. In our setup, the receivers are able to exchange messages over noiseless conference links of finite capacities, prior to decoding the messages sent from the transmitter. We first find the capacity region of the physically degraded BC with cooperating receivers. Then, we derive an achievable rate region for the general BC with three independent messages - two private messages and a common message, where the receivers hold a K-cycle conference. Additionally, we consider a special case of the general setup, the case of the general BC with just a single message. For this case we obtain explicit rate expressions. We also identify two scenarios in which these explicit rate expressions achieve capacity.
We then consider the discrete, memoryless, multiple-relay channel and derive an explicit achievable rate expression based on the EAF scheme. This expression is amenable to numerical evaluation. We demonstrate the benefits of this result via a discrete memoryless multiple-relay channel example, in which it is superior to multi-relay decode-and-forward. Finally, we consider the Gaussian relay channel with coded modulation at the transmitter and an orthogonal relay-destination link of finite capacity. Here we show that an EAF strategy implementing a three-level quantization outperforms the Gaussian quantization commonly used to evaluate the rates that the EAF scheme achieves in this scenario.

title: Life history and genetic diversity in desert reptiles and amphibians
abstract: Kelly R. Zamudio, Harry W. Greene, Monica A. GeberThe overarching goal of my dissertation research is to understand the link between organismal biology and patterns of population genetic structure across temporal and spatial scales. I focus on three vertebrate species that inhabit the deserts of the southwestern United States and that have habitat requirements and life history traits likely to promote population genetic differentiation.
Chapter one examines genetic structure in a lizard endemic to sand dune patches within a shinnery oak dominated landscape in eastern New Mexico. I used mitochondrial DNA and microsatellite markers to examine the effects of historical and contemporary processes on genetic structure across the geographic range of Sceloporus arenicolus. I found three main genetic clusters based on mitochondrial data with significant population differentiation within each group at microsatellite loci. These data suggest that specialization on and colonization of the shinnery oak ? sand dune landscape may be relatively recent and that the distribution of suitable habitat at fine scales may be less important to population connectivity than the persistence of larger networks of suitable habitat patches.
Chapters two through five address the maintenance and distribution of genetic diversity within and among breeding ponds for two syntopic anurans in Arizona and New Mexico. I examined the consequences of reproductive skew and larval mortality on the persistence of genetic diversity across generations and among breeding aggregations of the Great Plains Toad (Bufo cognatus) and Couch?s Spadefoot Toad (Scaphiopus couchii). Reproductive skew results in reduced genetic diversity in some, but not all, populations of both

species, with a greater effect in larger ponds of B. cognatus. Larval mortality influences genetic diversity only when mortality rates are extremely high or when the larval duration is prolonged. I found high effective population sizes and only weak genetic differentiation at large geographic distances in contrast to expectations based on within pond patterns, desert landscapes, and the scale of genetic structure found in other amphibians. In these desert environments, amphibians are remarkably well-connected by gene flow despite a pronounced effect of within pond processes on the maintenance of genetic diversity.National Science Foundation, Budweiser Conservation Scholarship, American Museum of Natural History, American Society of Ichthyologists and Herpetologists, Edna Bailey Sussman Internship, Sigma-Xi, Liu Memorial Award, Orenstein Fund, Cornell University Department of Ecology and Evolutionary Biology, Upstate Herpetological Society, Summer Institute of Statistical Genetics, Cornell University Graduate School

title: EFFICACY OF A CONTINUOUS PASSIVE MOVEMENT CHAIR SEAT ON TORSO MOVEMENT, BACK COMFORT, AND TASK PERFORMANCE
abstract: It has been shown that prolonged sitting and maintaining rigid postures can induce and exacerbate back pain. Postural fixity can have painful and debilitating implications including spinal shrinkage, increased intervertebral disc pressure and edema in the legs. Incorporating movement within a chair?s seat in the form of continuous passive movement (CPM) has been shown to assuage these physiological effects. However, apart from physiological studies, measuring effects of task performance, back pain, personal comfort, motion sickness, and the extent of torso movement are sparse. Experiment 1 measured the affect of CPM built within a chair's seat pan on these factors by comparing static and CPM conditions among 36 participants, half of whom had pre-existing back pain. Participants performed 3 work related tasks separated by 2 relaxation tasks, during two one-hour sitting conditions: one static and one CPM. The seat pan was set at a constant speed setting #4 throughout the CPM condition. Torso and seat pan movement were recorded using nano-accelerometers; a general comfort rating scale (GCRS) and a body map instrument were used to measure body discomfort over 6 collection times throughout the testing session; speed and error rate were used to measure typing, writing, and mousing performance; and a post-test questionnaire measured psychological and personal comfort, including measures of motion sickness.
Results showed that CPM did not statistically significantly affect participant performance or back pain (p>.05). There were statistically significant differences between personal comfort measures relating to postural stability (p<.000), postural instability (p<.003), limitations in writing and typing (p<.001), feelings of nausea (p<.023), and dizziness (p<.024) between the static and CPM conditions. Feelings were worse in the CPM condition for all variables. There were no statistically significant differences in questionnaire responses between those with and without back pain (p>.05) for either condition. Results further showed that participant?s torsos moved more while sitting in the CPM condition [F(3.334, 106.687)=17.285, p=.000] and while performing active versus passive tasks [F(1, 32)=26.531, p=.000]. Looking at open-ended comments specific to the chair?s CPM, there were more comments in disfavor (n=28) than in favor of the motion (n=14), and, when asked to reflect on the sitting experience, participants commented more negatively (n=46) than positively (n=28). Overall, people without pre-existing back pain commented more negatively on the chair?s motion (n=25) than those with back pain (n=18).
The first experiment maintained a constant speed setting #4 within the seat pan, restricting participants from manipulating the speed controls according to their personal preferences. A second experiment complemented this experiment by giving participants control over the speed setting to test preferences for specific speeds of chair seat pan movement according to particular task demands. This second experiment tested 12 participants with pre-existing back pain. Participants experienced similar protocol as the first experiment, except

participants were allowed to manipulate the chair?s speed and the nano-accelerometers were not used.
Results showed that people preferred having no motion during performance tasks (writing, typing, and using the mouse) and a moderate to low speed for passive, relaxation tasks (movies). Subjective responses were similar to Experiment 1. Overall, there were more negative (n=20) than positive comments (n=11) when asked to reflect on the sitting experience. These comments were almost exclusively related to the movement of the chair?s seat pan.
Results for Experiments 1 and 2 suggest that CPM may be best applied intermittently, allowing users to vary the speed settings according to task demands and comfort level. This has broad application to work places where traditional work breaks, such as walking, stretching, and standing, may be difficult to execute, or for individuals who are sedentary for long durations, such as truck drivers or wheelchair bound individuals.

title: Learning Culture Through a Musical Practice with Manding Jalis in New York
abstract: LEARNING CULTURE THROUGH A MUSICAL PRACTICE WITH MANDING JALIS IN NEW YORK
Lisa Karen Feder,
Ph.D. Cornell University 2007

This study depicts the music and culture of Manding jalis in New York through the perspective of non-African New Yorkers who interact with them. The non-Africans, the author included, move through the cross-cultural learning process as they attend live jali musical performances and learn to play and perform this music themselves. Jali refers to a person born into a particular caste and specific family lineage in the Manding region of West Africa. In Western literature, jalis are described as musicians, singers, oral-historians, advisers, diplomats, ceremony participants, teachers, and bards, among other things (Hale 1998; Charry 2000; Hoffman 2000). This dissertation depicts jalis who play the balafon, the kora, and the guitar in New York. Up to date, there is almost no literature on the topic.
The author applies Gregory Bateson?s notion of cultural ?ethos,? construed as schismogenic balances of tension and resolution, to both musical and non-musical social aspects of culture (Bateson 1972). Meter and rhythm create tensions and resolutions in people?s minds and bodies, giving them a common frame of reference. Simultaneously, participation in music exposes our cultural proclivities. This makes it an ideal place to begin the cross-cultural learning process. From the live music scenes, we then explore how music students learn to produce cross-rhythms and looping layered melodies as well as more subtle nuances in ?feeling,? or groove. Students learn how to learn, think, and play the music according to the Manding jali?s perspective. We apply these musical lessons as we become increasingly involved in the culture, at large.
This study uses an alternative methodology of a reflective practice (Sch?n 1987) in which the author is the primary participant. She moves from a music student, an organizer of balafon workshops to a friend, a patron, an agent, a marraine, and ultimately, a jatigi in jali society. The analysis is interlaced with antidotes of interpersonal experiences between Manding jalis, the author, and other participants. In conclusion we see how non-Manding and Manding music and culture cross-influence one another as they interrelate in the multi-cultural music scene in New York.

title: TRANSIENT BEHAVIOR OF THE PLANAR-FLOW MELT SPINNING PROCESS WITH CAPILLARY DYNAMICS
abstract: Paul H. Steen, Timothy J. Healey, Nicholas J. Zabaras, Steven J. Weinstein.Planar-flow melt spinning (PFMS) is a single-stage rapid manufacturing technique for producing thin metal sheets or ribbons. During the processing molten metal flows through a nozzle onto a moving substrate where a puddle is formed. This study focuses on the time dependent behavior of the process and looks at the puddle dynamics during the cast. Understanding how the issues of heat transfer, fluid flow and contacting dynamics influence the quality of the cast ribbon are the primary focus of the study. The commercial acceptance of PFMS requires ribbons to be cast with good quality (e.g. uniform thickness).
There are a large range scales that are relevant to the ribbon product. Thickness variations occur on the macro-scale over the length of the cast (50 m). There is a steady decrease in ribbon thickness over the length of the cast. There is also a periodic variation on the length scale of the wheel circumference (2-3 m). Steady mass, momentum and energy balances are used to understand these long length-scale thickness variations.
There are also thickness variations that occur on smaller scales, cm to mm. A periodic thickness variation across the width of the ribbon is a common defect observed in our casting, referred to as the cross-wave defect. The molten metal puddle is subject to capillary vibrations. We find that these oscillations correspond to the cross-wave defect.
Motivated by the physics of the cross-wave defect, a more generalized problem of the vibrations of coupled capillary surface is identified. The motions of the puddle are similar to the classical problem of the vibration modes of a `plucked' sphere. In considering the possible modes of vibration for a droplet confined between two plates, we find a novel vibration mode where the center-of-mass oscillates. This model is extended to account for a droplet confined within a tube, with two sections of the droplet extending from each end. Restricting to quasi-steady interface shapes, we find a translational vibration mode which can occur with lower frequency than the traditional Rayleigh modes. The vibration frequencies are compared to experimental values.Eastman Kodak Graduate Research Fellowship, NSF DMI-0500311, -0500408.

title: Practical Coding Algorithms for Consensus Problems with Zero Asymptotic Rate
abstract: We consider the average consensus algorithm under the rate constraint communication network. Average consensus algorithms are protocols to compute the average value of all sensor measurements via near neighbors communications. The main motivation for our work is the observation that consensus algorithms offer the perfect example of a network communication problem where there is an increasing correlation between the data exchanged, as the algorithm iterates. Henceforth, it is possible to utilize previously exchanged data and current side information to reduce the demands of quantization bit rate for a certain precision. We analyze the case of a network with a topology built as that of a random geometric graph and with links that are assumed to be reliable at a constant bit rate. We explore the conditions on the quantization noise which lead to a consensus value whose mean squared distance from the initial average is bounded. We propose two main practical schemes and show that they achieve bounded convergence with zero rate asymptotically. We further investigate the problem under regular grid network assumption and observe that computational complexity of the schemes reduce significantly and global knowledge of the network connectivity assumption can be relaxed. Thus, we conclude that the proposed schemes become scalable under dense networks.

title: X-PINCH PLASMA DYNAMICS STUDIED WITH HIGH TEMPORAL RESOLUTION DIAGNOSTICS
abstract: The X-pinch plasma produces extreme material conditions that make it interesting both as a high-energy-density plasma and an x-ray source for imaging. These extreme conditions include high densities (near solid density, 10^23 ions/cm^-3 for Mo), high temperatures (above 2.5 keV for Mo), high energy densities (up to 10^12 J/cm^3), high x-ray power densities (up to 10^22 W/cm^3), small source sizes (which can be less than 1 micron in diameter), and short time scales for the x-ray radiation (less than 100 ps). These extreme conditions are difficult to produce in a laboratory setting and even harder to study. The X-pinch plasma is produced by driving a high current (100-500 kA, 100 ns FWHM pulse for our experiment) through two or more wires that cross at a point forming an "X." A magnetically driven z-pinch forms near the cross point allowing the X-pinch to reliably reproduce the conditions given above. As such, we present a range of experiments designed to study the conditions produced in the X-pinch plasma. Until recently many of the diagnostics used to study the X-pinch have not had the resolution (spatial or temporal) necessary to determine the actual size or duration of the X-pinch x-ray source. We present experimental results showing the temporal extent of the x-ray radiation produced by an X pinch using an x-ray streak camera with better than 10 ps resolution. We also present experiments designed to study the temporal and spatial relationship of the two different radiation sources (thermal and energetic-electron-generated) observed from an X pinch using a filtered diode array. In addition, we studied the plasma dynamics using both a multi-channel 150 ps, 532 nm (Nd:YAG) laser backlighting system and x-ray radiography (using an X pinch as an x-ray source). We correlate the observed plasma parameters (implosion and explosion rate, neck diameter, axial jet propagation speed, and coronal plasma axial modulation wavelength along the X-pinch legs) to wire material.

title: Proper Orthogonal Decomposition and Tomographic Analysis of Combustion Systems for Control Applications
abstract: Control of combustion systems is of considerable importance to the improvement of system performance and is currently an active field of research. An understanding of combustion system dynamics is crucial to the development of effective control systems. Combustion dynamics and control combine the different aspects of combustion research such as theoretical analysis of the governing equations and phenomena, computational simulation, modeling, and measurement using advanced sensors.
Investigation of the use of proper orthogonal decomposition to analyze combustion product fields and their associated dynamics is presented. Proper orthogonal decomposition is applied to CO2 number density and vorticity magnitude data from reacting rectangular jet simulations. The resulting eigenfunctions are used to develop physical insight of the vortex formations and dynamics of these jets and their related mixing and spreading characteristics. It is seen that different vortex structures are captured in the eigenfunctions and that CO2 and vorticity eigenfunctions are very similar indicating that vortex-driven mixing dominates in these jets. Using subsets of eigenfunctions with high information content, CO2 and vorticity magnitude distributions can be represented with relatively few eigenfunctions.
Results of research to develop and apply multiple line-of-sight absorption and emission tomography for the study of combustion and as a sensor for monitoring and control of combustion systems are reported. Absorption tomography can provide data on the state of macro-mixing in combustion systems that can influence system performance, e.g. efficiency, radiation signature, and pollutant emissions. The development of an IR laser absorption facility for rapid scanning tomography and the performance of the tomographic reconstruction technique, Adaptive Finite Domain Direct Inversion, are discussed. The development of a

sensor system for use in a practical combustion device is also addressed. Computational simulation of a combustor sector rig provided operating state conditions such as excited state population and temperature distributions. Emission tomography measurements were simulated using numerical line-of-sight integration of simulated excited state number densities of water for two emission transitions. Tomographic reconstruction was performed using Tomographic Reconstruction via a Karhunen-Loeve Basis to evaluate nine line-of sight measurement configurations and an optimal measurement configuration was selected. Operating state identification for control applications was investigated using the TRKB reconstructions.Office of Naval Research, Dr. Gabriel Roy (scientific officer), ONR grant # N00014-99-1-0447 //

title: Practical Applications of Phosphate Analysis in Household and Abandoned Settlement Archaeology: Case Studies from Ireland and New York State
abstract: Dr. Sherene Baugher, Dr. Thomas VolmanTesting for phosphates at archaeological sites has helped to guide the placement of archaeological excavation units in the past. Phosphate testing can assist archaeologists by pinpointing areas of elevated human activity. The technique, however, has only been used minimally in archaeological practice. Phosphate testing is not common due to the high laboratory cost of performing phosphate tests, and the relative ambiguity of results obtained from field-testing for phosphates. Archaeology would benefit greatly from a less expensive, more accurate method of phosphate testing. By slightly changing the standard field test for phosphate analysis it is possible to improve results. A revised method for phosphate testing also allows archaeologists to test sites to obtain the location of middens and other features, to identify land-use patterns, to locate new sites, and even discern chronology of a site, within a reasonable budget. Two case study analyses were performed to show how phosphate testing can be used in conjunction with archaeology. They were located at the Achill Archaeology Field School project site in County Mayo, Republic of Ireland, and at the Cornell University project site at Robert Treman State Park, New York State, United States of America.

title: Magnetism in Coaxial Palladium Nanowires
abstract: While bulk palladium is non-magnetic, several recent studies have shown that magnetism can occur in hcp Pd films, fcc twinned Pd nanoparticles, and Pd atomic strands. These studies show that small changes in Pd atomic configurations can induce magnetic properties. In this work, we examine coaxial palladium nanowires in an effort to determine the most stable configurations and their magnetic properties. Relaxed nanowire structures are found using density functional calculations in the plane wave basis. In several metallic systems such as gold, coaxial nanowires have proven to be the lowest energy configuration for ultrathin (< 1 nm) nanowires. We consider magnetism in these structures as a function of diameter and coaxial configuration. These results are also compared to fcc and hcp Pd nanowires of comparable diameters. We find that the (6,0) coaxial nanowire provides the most stable structure and exhibits a magnetic moment of 0.278 uB/atom.

title: ANALYZING THE EFFECT OF CROSS FLOW VELOCITY, UNIFORM TRANS MEMBRANE PRESSURE AND PH ON PERMEATE FLUX, RETENTATE COMPOSITION AND ENERGY CONSUMPTION DURING CROSS FLOW MICROFILTRATION OF SKIM MILK
abstract: Pasteurized skim milk at pH 6.50 and 6.00 was microfiltered at 50oC using 0.2-mm membranes. A factorial design of three cross flow velocities (CFV) of 5.3, 5.8, 6.3 ms-1 and three uniform trans membrane pressures (UTMP) of 68.9, 103.4, 137.9 kPa was utilized. High CFV combined with high TMP required the shortest time (up to 40%) to achieve a concentration factor (CF) of 8-10x. Starting flux was 20 to 50% higher at pH 6.50 when compared to pH 6.00 due to solubilization of micellar calcium and severe fouling at lower pH. Higher flux was always obtained by using the combination of high CFV and high UTMP, which results in high shear and 33% reduction in gel layer (CG) with back transport of rejected molecules into the retentate stream due to better (almost double) mass transfer coefficient (kc). Higher CFV also reduced whey protein retention by 33%. Cross flow microfiltration (CFM) at lower pH (6.00) reduced calcium retention and lowered calcium to true protein ratio by 50% at 10x, compared to 8x retentate at pH 6.50, though 10x retentate had 20% higher casein concentration. Higher UTMP helped maintain high flux and thus shorten the run time up to a CF of 6-7x, but resulted in severe fouling and a steep decline in flux and increased whey protein retention as the process was continued to higher concentrations (8-10x). Overall energy consumption was always lower due to shorter CFM process when skim milk was microfiltered to 8x at higher CFV and higher UTMP.

title: Modeling Post-Earthquake Restoration of the Los Angeles Water Supply System
abstract: Special Committee: Rachel A. Davidson, Thomas D. O'Rourke, Linda K. NozickThe purpose of this thesis is to develop a discrete event simulation model of post-earthquake restoration for the Los Angeles Department of Water and Power (LADWP) water supply system. Discrete event simulation, a new approach to modeling post-disaster lifeline restoration, offers many benefits for restoration modeling compared to alternative methods. The water supply system and restoration process are represented in great detail with few simplifications. The utility company's decision variables (e.g., number of repair crews, repair prioritization rules) are included explicitly, allowing exploration of their effects on the speed of the restoration. Restoration times are estimated separately for each region within the service area, and uncertainty in the process is modeled explicitly.
With a service area of more than 1,200 km2 and 12,000 km of pipelines, the LADWP water supply system is the largest municipal system in the United States. Extensive review of the LADWP water organization, water supply system, and post-earthquake restoration process was conducted. This review provided the basis for the restoration model. Crews, tasks, and the different phases in the restoration process came directly from discussions with LADWP personnel and the water organization's emergency response plans.
For a particular earthquake, the restoration model takes as input information about damage to the system and the resulting hydraulic flow, both of which are provided by the Graphical Iterative Response Analysis for Flow Following Earthquakes (GIRAFFE) model that was developed for the LADWP system (Shi 2006, Wang 2006). Throughout the restoration simulation, the model interacts with GIRAFFE periodically in order to receive updates of the system functionality at specific times as the restoration process proceeds and damage is repaired.
The restoration model provides several different types of output including system and subregion restoration curves; spatial distribution of restoration; material usage; crew usage; average time each customer is without water; and time to restore the system and subregions to 90%, 98%, and 100%. It can also include damage

uncertainty by combining the output from runs for multiple realizations of damage associated with a single earthquake. The model can be used to help estimate economic and societal losses due to water supply system outages, and to evaluate the effectiveness of possible restoration improvement strategies.
Ten simulations of the restoration model were run using real damage data from the 1994 Northridge earthquake as input, and the results were compared to the actual restoration that took place following Northridge. The average spatial distribution of restoration roughly matches what occurred in 1994. As in real life, the areas experiencing longer outages in the model are mainly in the north of the system service area or around the San Fernando Valley. The system restoration curves did not match exactly, as the range of outputs from all 10 runs of the restoration model shows that the restoration occurs too quickly, especially during the first day after the earthquake. Possible future model modifications that may improve the calibration are discussed.

title: Multi-site Action Research
abstract: Classical action research within single organizations has become a well established and differentiated approach since its inception more than six decades ago. Although new larger scale varieties of action research are beginning to develop, there is still a clear need to expand the scope of action research practice (Greenwood, 2002). Building on previous work, this paper develops multi-site action research (MAR) as a conceptually distinct variant of action research implementation with promising potential to fill the gap between the classical and coalition type varieties of action research. MAR is defined as involving the concurrent implementation of multiple distinct single-site action research processes, with a similar focus, and some level of coordination across sites. From a review of three relevant multi-site initiatives, a conceptual framework for the potential benefits of MAR is derived, and a model of the MAR implementation process is presented and discussed.

title: The significance of heavy-chain antibodies to camelid immunity
abstract: Camelids produce IgG isotypes that do not conform to the rules governing conventional antibody structures. Typically, immunoglobulins combine homodimeric heavy and light chains to produce characteristic tetrameric structures. Unlike IgG1, the camelid IgG2 and IgG3 isotypes do not incorporate light chains into their structures. These unusual antibodies, generally referred to as heavy-chain antibodies (HCAbs), comprise approximately 50% of serum IgGs, compatible with a significant role in camelid immunity. Hitherto, the effector functions of camelid HCAbs remain largely undefined primarily due to the dearth of available isotype-specific reagents. As it was our objective to investigate camelid HCAbs, we produced and characterized monoclonal antibodies that discern among the IgG isotypes produced by both llamas and alpacas. These reagents were employed in affinity chromatography, serologic analyses, virus neutralization assays, flow cytometry, and immunohistochemistry to differentiate between the B cell sub-populations that synthesize conventional and heavy-chain IgGs, determine whether expression of the different IgG isotypes was regulated differently, and to investigate the clinical and physiological relevance of HCAbs.
Our investigations led to the discovery of a novel IgG3 protein, and the production of immunological reagents that discern among two conventional IgG1, IgG2 and the two IgG3 HCAbs. We have documented that the B

cell sub-populations developed within similar lymphoid compartments during gestation. At birth, HCAbs obtained through colostrum contributed to the passive transfer of immunity that is critical in protecting the newborn until maturity of its immune system. Throughout life, the B cell sub-populations continued to occupy similar compartments, although, B cells that locate within splenic marginal zones expressed one sub-isotype of IgG1 exclusively. Also, follicular B cells within adult, ileal Peyer's patches expressed only the novel IgG3. In response to pathogen infections, camelid B cells elicited IgG2 to helminths and IgG3 to viral infections: IgG1 expression was ubiquitous. Anti-viral IgG2 were induced only by hyperimmunization. While IgG3 proved to be as potent as IgG1 in neutralizing activities, anti-viral IgG2 was ineffective. The data presented here document for the first time a dichotomy in the effector functions of camelid IgG2 and IgG3 HCAbs.

title: NOVEL SILICON AND CARBON NANOTUBE ELECTRONIC DEVICES: TECHNOLOGY, STRUCTURE AND PROPERTIES
abstract: Originating in an effort to advance electronics into nanometer scale regime and towards higher integration, several novel electronic devices are described here for computation and data storage applications. These include super-self-aligned separately-gated double-gate transistors, a cross-coupled bipolar injection memory (xFET) and top/back-gate carbon nanotube transistors. Hybrid integration of silicon and carbon nanotube electronics are demonstrated for the first time to show a viable direction for future electronics to extend technology reach for new scientific and engineering fields.
The Super-self-aligned separately-gated double-gate field-effect transistor (FET), featuring strained silicon channel, thick source-drain region and buried-interconnected gate, have been made for both polarities n- and p-type using a novel approach that helps advance silicon CMOS technology to nanometer scale. All these features help alleviate the power consumption issues for future nanoscale CMOS transistor where performance degrades due to short channel effects and the loss of device threshold voltage control.
A novel non-volatile memory device?xFET?is developed with several charge injection mechanisms to allow a variety of operational capabilities and provide significantly faster programming/erasing speed. Nanoseconds programming time has been achieved through hot electron injection. In a crossed nFET/pFET configuration, the new device features a four-terminal bipolar structure with a top floating gate used as the charge storage node. The silicon-on-insulator (SOI) technology in the device development ensures excellent CMOS compatibility.
With techniques borrowed from silicon ULSI technology, carbon nanotube field-effect transistor (CNFET) with either back-gate or self-aligned top-gate structure has been developed to improve device performance and integration. For back-gate CNFET, combined analysis of device?s transient and transfer characteristics in contrasting environment (in air or in vacuum) show distinct ambient effects on the device carrier transport properties. High frequency pulse measurement is employed to produce intrinsic device transport properties through elimination of hysteresis and 1/f noise.
Integration of carbon nanotubes transistor on top of nMOS transistors can provide compact circuit components. One example?a logic NOT gate is demonstrated in a monolithic integration of p-CNFET on top of nMOSFET. This integration scheme is an example that combine different technologies to make new applications possible on a robust silicon technology platform.Center for Nanoscale System

title: BIOLOGICAL CONTROL OF THE TARNISHED PLANT BUG, LYGUS LINEOLARIS (HEMIPTERA: MIRIDAE), BY PERISTENUS SPP. (HYMENOPTERA: BRACONIDAE), IN NEW YORK APPLE ORCHARDS
abstract: Lygus lineolaris is a pest of many economically important crops. While the species comprising the Peristenus pallipes complex are native parasitoids of L. lineolaris, they do not provide adequate biological control of L. lineolaris. As a result, the European parasitoid, Peristenus digoneutis, was introduced in forage alfalfa. Peristenus digoneutis successfully dispersed from forage alfalfa to strawberries, suggesting that P. digoneutis may disperse into other high value crops. In apples, L. lineolaris feeding causes puncture wounds, scabs or cat facing on the fruit.
The success of a classical biological control introduction is dependent on both monetary and ecological costs and benefits. The dispersal and persistence of P. digoneutis into multiple crops is necessary for monetary benefit. Furthermore, if pesticides disrupt classical biological control no monetary gain can be made. In addition, an ecological cost of classical biological control is displacement of native species. The objectives of this study are to-1) establish the presence of the introduced parasitoid, Peristenus digoneutis, in New York apple orchards, 2) evaluate changes in rates of parasitism of L. lineolaris by native and introduced Peristenus spp. since the initial dispersal of P. digoneutis into western New York, 3) determine how four pesticide regimes- standard, reduced risk, organic and abandoned orchards- affect Peristenus spp. parasitism.
During this two year study L. lineolaris were collected from New York apple orchards treated with standard, reduced risk, organic insecticides. This is the first record of P. digoneutis parasitizing L. lineolaris in apple orchards. When compared to rates of parasitism collected from strawberries in 1999 there is an increase in the total L. lineolaris parasitism by Peristenus spp. in western New York. Additionally, there was a reduced rate of parasitism by native parasitoids in the P. pallipes complex, suggesting that P. digoneutis may be competitively displacing natives. Insecticide treatment had a significant effect on rates of Peristenus spp. parasitism. When compared to standard insecticide regimens there was significantly higher parasitism in reduced risk when compared with standard orchards. Conversely, there was significantly less parasitism in organic orchards when compared to standard orchards.USDA-ARS cooperative agreement 58-1926-0-039

title: The Effects of Higher Admission Standards: An Analysis of Intercollegiate Athletics
abstract: The objective of this study is to examine the effects of increasing admissions standards on college enrollment and graduation rates among minority student-athletes. Intercollegiate athletics has traditionally provided increased access to college for minorities, especially African-Americans. In 1996, the National Collegiate Athletic Association enacted a policy that increased the minimum required high school GPA and combined SAT or ACT score for all entering student-athletes at Division I schools. Division II schools were unaffected by the policy, providing a plausible set of control schools with which to compare the impact. Although the target goal of the policy was increasing graduation rates of Division I schools, the current study provides evidence that graduation rates did not significantly increase among Division I schools. Furthermore, as a result of the increased standards for Division I schools, more student-athletes attended Division II schools and the schools experienced a subsequent increase in graduation rates. One possible explanation for this effect is that student-athletes of marginal academic quality may have ?matched? better with Division II schools and thus increased their likelihood of graduation.

title: The segmentation of nonsolid pulmonary nodules in CT images
abstract: Nonsolid nodules are a common radiographical finding in high resolution CT images of the lung. A main factor in determining a nodules malignancy status is the change in the nodule size over time. A method for automatically segmenting a nonsolid nodule from CT images is presented in this thesis. Precise image segmentation is a prerequisite for determining the volumetric growth rate from multiple image scans and the corresponding nodule malignancy status.
There has been limited previous work on a segmentation technique for nonsolid nodules. The methods that have been proposed have lacked clinical validation with a radiologist ground truth and often include smaller datasets. The method in this thesis directly compares radiologist ground truth with our automated method and examines the consistency of growth measurement for further validation.
The segmentation method consists of three stages; bilateral noise reduction, a probability based voxel classifier and geometric vessel removal. Parameter optimization and validation of the segmentation algorithm is facilitated with a dataset of 20 nonsolid nodule images in which a radiologist has established ground truth by outlining the boundary of the nodule in each image that it is visible. The optimal parameters were determined using the overlap metric and a training/testing methodology. The automated method achieved an average overlap of 0.43 with the radiologist ground truth.
An experiment was conducted to determine whether the radiologist manual boundaries or the automated segmentations were more consistent at measuring the volumetric growth between three time scans of the same nodule. Results were determined for two different growth models (exponential and linear) on a dataset of 25 nonsolid nodules. The growth variation of the automated method was found to be 1.87 compared to the radiologist growth variation of 3.00. This suggests that, if the assumption of consistent nodule growth holds for nonsolid nodules, then the automated method provides a more precise growth rate estimate than the radiologist markings.

title: ON THE COMPUTATION AND APPLICATION OF MULTI-PERIOD SECURITY-CONSTRAINED OPTIMAL POWER FLOW FOR REAL-TIME ELECTRICITY MARKET OPERATIONS
abstract: This work concerns the formulation and solution of a multi-period security-constrained optimal power flow problem for real-time electricity market operations. The solution of the proposed problem is intended to be part of the core pricing procedure for electricity trading in open markets where real energy, reactive energy, voltages support, and other system resources and services can all be traded in discrete bids and offers. Traditionally, real-time dispatching operations only involve solving single-period security-constrained optimal power flow problems. This work demonstrates the need for solving multi-period security-constrained optimal power flows. The nonsmoothness of the offer/bid-driven optimal power flow problem is studied. Three techniques, namely, a trust-region based augmented Lagrangian method, a step-controlled primal-dual interior point method, and a modified constrained cost variables method, are developed for reliable and efficient computation of large-scale nonsmooth optimal power flows. Numerical studies show that these techniques are reliable and better than some existing ones. To reduce the computational complexity, two decomposition techniques are proposed and studied. In the first one, the auxiliary problem principle method is extended to handle inequality constraints created from generator ramping limits. In the second one, binding time-coupling and contingency-coupling constraints are estimated, ranked, and filtered before the computation is decomposed and parallelized using standard block matrix computation techniques. According to experimental

results, the most promising way of solving large-scale multi-period security-constrained optimal power flow problems in real time is to combine the second decomposition method with the modified constrained cost variables method. The optimal power flow formulation and relevant computation techniques proposed in this work balance the needs for: (1) deterministic convergence, (2) accurate computation of nodal prices, (3) support of both smooth and nonsmooth costings of a variety of resources and services, such as real energy, reactive energy, voltage support, etc., (4) full active and reactive power flow modeling of large-scale systems, and (5) satisfactory worst-case performance that meets the real-time dispatching requirement.

title: MOLECULAR ASSESSMENT OF BTH TREATMENT IN PETUNIA, POTATO AND TOMATO
abstract: Induced resistance by chemicals such as benzothiadiazole BTH (Syngenta Inc) mimics the biological activation of Systemic Acquired Resistance (SAR) by necrogenic pathogens, taking the place of salicylic acid (SA) in the SAR signal pathway, inducing the same molecular markers and range of resistance. Previous work in our laboratory found that BTH activates resistance against late blight caused by P. infestans, on petunias and tomatoes while it did not activate resistance against the same pathogen on potatoes, suggesting that the spectra of resistance activated by BTH are very crop and pathogen specific. My goal was to understand the molecular mechanism by which BTH mimics the SAR response and further understanding why BTH works in some plants and not others. To address this question I used microarray technology to identify the genes expressed in response to BTH in petunias, tomatoes and potatoes. I selected three candidate genes (cysteine protease, acidic chitinase and PR1-a) to characterize further by silencing using Virus Induced Gene Silencing (VIGS). My hypothesis was that silencing of these genes will reduce the resistance response in plants observed after BTH treatment against P. infestans. However, silencing of cysteine protease, PR1-a or acidic chitinase II individually did not reduce the effect of BTH on plants. The lack of phenotype after silencing PR1-a supports previous conclusions from our lab that partial resistance to P. infestans in tomato is not dependent of the SA pathway.

title: THE INTESTINAL-CELL MONOLAYER OF THE DOG (CANIS FAMILIARIS) AND MALPIGHIAN TUBULES OF AEDES AEGYPTI: POWERFUL IN VITRO MODELS FOR STUDYING EPITHELIAL TRANSPORT
abstract: Homeostasis of the internal environment of vertebrates and invertebrates is maintained by a collection of organs involving the gastrointestinal system, the renal system and the pulmonary system, whose surfaces facing the external world are covered by a layer of highly polarized epithelial cells as the barrier and sites for substance exchange between body and the external world. As most studies on epithelial transport are done in animal cell- or tissue-models, this dissertation is set to address questions on two in vitro epithelial models: monolayers of cultured epithelial cells and Malpighian tubules of insects.
In the field of epithelial transport across mammalian small intestines, most of the cell monolayers that have been used in the past are abnormal: they are either derived from cancerous cells or poorly differentiated compared to normal tissues. By strictly controlling cultural conditions, we successfully developed an epithelial cell culture derived from normal dog jejune with full differentiation, which can form cell monolayers with remarkable resemblance to the normal small intestinal epithelia in morphology, expression of the junctional proteins and membrane transporter, and electrophysiological properties. Furthermore, different channels

can be induced when the cell monolayer is treated with different hormones and agents, suggesting its wide application in basic and applied research studies.
Malpighian tubule of the yellow fever mosquitoes Aedes aegypti has been the epithelial transport model in our lab for more than twenty years. The V-type H+ ATPase is thought to provide driving force for transepithelial electrolyte and fluid secretion in Malpighian tubules. Here we immunohisochemcially localized the proton pumps to the apical membranes of the mitochondria-rich principal cells of the Malpighian tubules, and measured enzymatic activities of the V-type H+ ATPase as 50~60% of the total ATPase activities. In comparison the activities of the Na+/K+ ATPase were almost undetectable.
To understand the functions of Malpighian tubules, we also modeled the tubule into equivalent electrical circuits. However in our previous studies, the model was incomplete, as contribution of gap junction resistance between Malpighian tubule cells to the circuit has never been revealed. In this dissertation, we accurately measured the electrical resistance of gap junctions in a single cell by circuit analysis and rectified the values of all the electrical elements in our previous model. The equivalent electrical circuit has for the first time become complete. The results also show that gap junctions in Aedes Malpighian tubules are impermeable to the fluorescent dye Lucifer yellow CH, sensitive to the metabolic inhibitor dinitrophenol, while not so sensitive to elevated intracellular [Ca2+].

title: Renegotiating Resistance: African Diaspora Film and the Discourse of Third Cinema
abstract: Emerging out of the context of the tricontinental revolution of the 1950s and 1960s, Third Cinema refers to a host of film practices from Latin America, Africa and Asia with the political intent of the decolonization of culture. For contemporary filmmakers and critics, however, the discourse of Third Cinema cannot be easily applied to contemporary times and contexts. In this thesis, I attempt to reconcile the discourse of Third Cinema with contemporary African diaspora film practices in a renegotiation of cinematic resistance.
Proceeding from Gilles Deleuze's theory that the evolution of cinema from classical to modern materialized out of the historic rupture produced by World War II, my thesis locates another rupture in the dissonance between Third Cinema and contemporary African diasporic filmmaking. The lingering effects of neo-colonialism and the process of globalization have rendered older categories to describe the world inadequate, and filmmakers all over the world are actively engaged in decentering the grand narratives of Western and Third Cinemas. Because this deconstructive process is most often associated with the diasporic condition by postcolonial theorists, I argue that a "diasporic turn" has occurred within cinema that shapes contemporary film narratives and aesthetics. Although my use of the term "diaspora" is conceptual rather than geographical, in my thesis the African diaspora, historically constructed through the process of forced and voluntary migration, operates as a unit of analysis for exploring the "diasporic turn." Through the analysis of three films from the African diaspora, my thesis not only explores the postcolonial and diasporic issues with which the discourse of Third Cinema must reconcile in order to have contemporary relevance, but it also gestures towards a new discursive framework for characterizing contemporary African diasporic film practices.

title: BIDDING ON URBANITY WITH BUSINESS IMPROVEMENT DISTRICTS:
abstract: BIDDING ON URBANITY WITH BUSINESS IMPROVEMENT DISTRICTS: RE-MAKING

URBAN PLACES IN WASHINGTON, DC
Susanna Francesca Schaller, Ph.D.
Cornell University 2007
"The livable city," one that offers street-level, neighborhood life, cultural and ethnic diversity as well as a broad choice of entertainment venues and businesses, has become the catch-all phrase to encapsulate the vision of city life employed to attract a class of potential urbanites who are viewed as key to maintaining and bolstering the tax-bases of fiscally strapped city governments (Florida 2002, Kearns and Philo 1993). Harnessing this competitive advantage that cities have over their suburban neighbors requires cleaning up commercial spaces and marketing images free of deterioration (Florida 2002, Philo and Kearns 1993, Holcomb 1993). Business improvement districts (BID) have become a tool to secure perceptions of safety and attractiveness for new residents, businesses, and tourists and to stimulate reinvestment in urban retail and residential development. BIDs have become key actors in planning for and managing these efforts.
BIDs privilege the rights of commercial property owners in the governance of local districts and draw artificial boundaries between the residential and commercial life of neighborhoods. Thus, their uniform application, particularly, in ethnically and economically diverse urban neighborhoods, masks struggles over neighborhood boundaries, identities, property values and rents. The following questions guide this dissertation:
What interest-alignments underlie the wide-spread institution of place-making economic development strategies such as BIDs?
o For whom and by whom are these urban places produced?
o Whose visions of place are incorporated and whose are left out?
In order to address a specific lacuna in the literature on BIDs, this dissertation examines the BID establishment process that unfolded in one of the most ethnically and economically diverse areas in Washington, DC. In order to understand local level interest alignments that support the formation of BIDs in the context of larger economic and political processes affecting urban governance, the research is designed as a nested case study based in the extended case method, elaborated by Burawoy (1991). This design places the neighborhood case study area within the context of a shift toward entrepreneurial city governance in DC, keeping in mind the historical layering of territorial struggles that shape DC?s geographic, social and political landscape (Harvey 2005).

title: TOPICS IN THEORETICAL ASTROPHYSICS: PRECESSION OF WARPED DISKS, OSCILLATIONS OF PRESUPERNOVA STARS, AND THERMAL EVOLUTION AND NUCLEOSYNTHESIS OF YOUNG NEUTRON STARS
abstract: This thesis consists of three parts. In the first part, we study the magnetically driven precession of warped disks. An accretion disk around a rotating magnetized star is subjected to the magnetic torques that induce warping and precession of the disk. We study the global hydrodynamical warping/precession modes of the disk under the combined influences of the magnetic torques, relativistic frame dragging, and the classical precession due to oblateness of the neutron star. We apply our analysis to two types of accreting systems: low-mass X-ray binaries (LMXBs) and accreting X-ray pulsars. We argue that some features of low-frequency quasi-periodic oscillations (QPOs) in LMXBs and milli-Hertz QPOs in accreting X-ray pulsars can be explained by the magnetically driven precession of warped disks. The second part is related to the hydrodynamically-driven mechanism for asymmetric supernova explosions / neutron star kicks. We explore the possibility that the gravity modes in the core of a presupernova star may be amplified in the silicon burning shell to produce the global asymmetric perturbations that lead to an asymmetric supernova explosion. By performing a linear analysis of the oscillations in the cores of presupernova stars, we estimate

the growth/damping rates of the modes. We find that most of the modes are damping modes with a few exceptions. We also find that, even for a growing mode, the timescale of mode growth is much longer than the remaining time before the core collapse. We conclude that the gravity modes in a presupernova core cannot provide the global asymmetric perturbations that lead to an asymmetric supernova explosion. In the last part, we attempt to predict the innate chemical composition of a neutron star atmosphere. There has been great progress in X-ray observations and now thermal radiation from neutron stars is being studied in detail. There has also been significant progress in modeling thermal spectra from neutron stars. However, the unknown chemical composition of the neutron star surface is assumed in these models. Our goal is to predict the chemical composition of a neutron star atmosphere by evolving its thermal structure and the chemical composition from the earliest possible time. We study necessary steps to achieve this goal. We study models for a static atmosphere of a young neutron star, cooling of the bulk of a young neutron star, the nuclear statistical equilibrium abundances, nucleosynthesis, and the possible role of diffusion.

title: Electrical Stimulation for Pain Suppression: Mathematical and Physical Models
abstract: Master of Engineering thesisFinite element models of increasing complexity were generated in the ANSYS finite element modeling program to determine the electric field and current properties in the body as a result of the transcutaneous electric nerve stimulation (TENS) device. The initial models consist of one-, two-, and three-layer structures, and the final model was a 7,415 node two-dimensional model of the human arm. To validate the ANSYS calculations, one-, two-, and three-layer phantom models were developed using agar, deionized (DI) water, and sodium chloride in varying concentrations. A summing amplifier was built to combine multiple stimulating waveforms at different frequencies from two function generators at two frequencies F1 and F2. Current measurements from the phantom models were compared to ANSYS calculations on corresponding finite element models. The ANSYS program was validated for modeling of single-layer models. Multiple layers of gels of different resistivity exhibited ion leaching problems which made them unsuitable as phantom models. It is necessary, therefore, to develop and validate an alternative phantom model for modeling electric field and current properties of multi-layer systems.
A technique was developed for transforming cross-sectional images of body parts into mesh diagrams suitable use in ANSYS. Body images from ?The Visible Human Project? were taken and processed such that eight different tissue types and their location could be identified. Electrical properties were determined for muscle, skin, fat, cortical and cancellous bone, blood, connective tissue, and nervous tissue for use in the ANSYS simulation models. A cross-section of a male arm was processed and analyzed.Dr. Dan Aneshansley

title: Increasing Evapotranspiration Trends Over the Mississippi River Basin
abstract: Recent research suggests that the evapotranspiration rate (ET) over much of North America has increased over the past 50 years; however there is not a consensus on why the rate is increasing. Most of these studies have focused on annual trends starting around 1950. This study considers (1) whether or not published ET rates would be affected by the addition of the 1940s to the dataset, (2) changes in monthly stream flow and precipitation patterns that could affect the rate of ET and whether there are months driving these annual trends, and (3) whether there are certain areas in the watershed driving this trend. This study considers the hydrological cycle for the Mississippi River Basin from 1940-1999 to show that ET rates have

increased. However, when considering trends starting in the 1940s, the trends are not nearly as strong as the trends of the 50 years period 1950-1999 with an increase of 0.29 mm/yr rather than 0.88 mm/yr. Monthly analyses showed that summer months, when potential ET is the highest, have a persistent increasing trend in precipitation, which probably contributes most significantly to overall increasing ET. The most dramatic and longest term shifts appear in July, where, for the period of 1940-1999, there is an increase of 0.30 mm/yr, July accounts for nearly 100% ET increases. However, this drops to 15% for the period of 1950-1999. These results reinforce the studies showing an accelerated hydrologic cycle over North America and, surprisingly, that much of the ET increase can be attributed to increases in July. Also it can be seen that the areas of the Great Plains and Rocky Mountains are the areas driving this increase, especially the Arkansas, Red, and White River valleys.

title: A Storm Water Management Model to Predict Runoff and Streamflow in the Pennichuck Brook Watershed
abstract: Due to continuing property development in the area much of the Pennichuck Brook Watershed has transformed from wooded areas and farmland into residential and commercial districts with a large amount of impervious area. The result has been increased runoff and pollutant loadings to the chain pond water supply system operated by Pennichuck Water Works. The new EPA Storm Water Management Model (SWMM) Version 5.0.006a was used to assess the condition of this watershed. Utilizing the aquifer sub-model the SWMM model was calibrated to the Pennichuck Brook Watershed. Due to the large volume of precipitation percolating into the ground, the aquifer component was necessary to determine groundwater flow to surface waters. Stream gaging stations were set up and streamflows were measured to develop stage discharge curves for each of the nine gaging stations throughout the watershed. Water level data loggers were installed at these sites where stream levels were recorded from September 29, 2005 through May 4, 2006. These levels were converted into continuous streamflow records that were subsequently used in model calibration and validation procedures. Problems encountered in this project included heterogeneities in the aquifers and heterogeneities in the precipitation neither of which were modeled due to lack of sufficient data. Additionally, there were several gaps in the streamflow records as a result of wildlife interference and datalogger batteries failing. The calibrated SWMM model provides a reasonably accurate model for predicting runoff and streamflow in this watershed. The coefficients of determination were 0.50 and 0.86 for the model calibration and validation, respectively. On average the model predicted lower streamflow rates and volumes than were observed in the field most likely due to inter-watershed groundwater flow.

title: SGER: Planning Information Infrastructure Through a New Library-Research Partnership [final report]
abstract: document contains most significant sections of a final report to NSF submitted 2007-01-21.The purpose of this Small Grant for Exploratory Research was to explore the issues surrounding a new type of collaboration between scientists and research libraries to support the preservation, discovery, and sharing of primary research data. With recent advances in computing and telecommunications technology, the stage is set for a major shift in the way science is conducted. Researchers and funding agencies are recognizing

that data can be valuable for purposes beyond the studies in which they were originally collected, and some agencies are requiring data sharing plans as prerequisites for funding support. There is, however, a lack of established infrastructure to support the services necessary for handling research data. This grant investigated the premise that research libraries might serve as natural partners in addressing the data management needs of the communities they serve.This material is based upon work supported by the National Science Foundation, Grant No. 0437603. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

title: Stepping Out: The Expanding Role of Catalogers in Academic Libraries and Academic Institutions
abstract: The stereotype of the cataloger as an isolated, back-room practitioner has persisted among many in the profession, despite years of evidence to the contrary. This paper examines some roles that catalog librarians have long played within their institutions and outside of technical services. The example of the various roles catalogers have assumed at Cornell University Library is used to illustrate some of the possible ways catalogers contribute to the research and teaching missions of the institution that extend beyond their traditional roles. The paper also touches briefly on possible future opportunities for catalogers to participate in the intellectual community of the university

title: The Effects of Emotion on False Memory Production
abstract: This study seeks to investigate the effects of emotion on false memory production. 114 undergraduate college students participated in the study. Subjects were given an emotion induction task that induced positive, negative, or neutral moods by rating person descriptive words taken from the Dumas norms. Each subject was then asked to listen to lists of study words taken from the Deese-Roediger-McDermott paradigm and was then given an immediate recognition memory test. One week later, subjects were given a delayed recognition memory test to measure the degree of forgetting. Results indicate that on the immediate test, although there were no differences observed across emotion conditions for true memory, participants in the negative emotion condition were more prone to produce false memories than those in the positive or neutral conditions. In addition, there was no main effect of emotion for the immediate test, but there was one for the delayed memory test. It was found that acceptance rates of both targets and critical distractors decreased for participants in the negative emotion condition relative to positive and neutral conditions. It was also found that one could inoculate the effects of forgetting on a delayed memory test by giving subjects a prior memory test.

title: Progress Report: Understanding Sources and Sinks of Nutrients and Sediment in the Upper Susquehanna River Basin
abstract: Principal investigators:
Robert Howarth, Lead Principal Investigator, Ecology and Evolutionary Biology; Alice Pell, Animal Science; Johannes Lehmann, Crop and Soil Sciences; Roxanne Marino, Ecology and Evolutionary BiologyDuring recent decades, the amount of nitrogen flowing into surface waters and estuaries in the northeastern USA has increased 10-fold or more. In estuaries such as the Chesapeake Bay, such large increases in nitrogen are severely damaging populations of aquatic plants and animals, and also increasing harmful and toxic algal blooms. Most of the coastal waters of the USA are seriously degraded. At the global and national scale, agriculture is the major source of nitrogen pollution. However, atmospheric deposition is also a major source in many regions, and it contributes 25 percent to 50 percent of the nitrogen inputs to Chesapeake Bay.
The Susquehanna River is the largest river east of the Mississippi in the USA, the largest tributary of Chesapeake Bay, and the single largest source of nutrients to the main stem of the Bay. Therefore, better understanding of the sources and sinks of nutrients and sediment in the Susquehanna River watershed will support better management of nutrients and water quality in the Chesapeake Bay. Research is needed urgently to identify the most important targets for nutrient reductions and the most cost-effective solutions.Funded by: United States Department of Agriculture, Cooperative State Research, Education, and Extension Service award number 2005-34244-15740.

title: Road Salt Loading in the Fall Creek Watershed
abstract: This project models the rising chloride concentrations in the Fall Creek watershed located near Ithaca, New York. Base-line salinization levels for freshwater in the northeastern United States have been increasing over the past several year and road salt has been identified as a possible primary source (Kaushal et al., 2005). Investigation is required to determine what detriment this may be causing to freshwater sources and environments. Data shows current concentrations in Fall Creek watershed to be 18.8 ppm as of 2003 (Bouldin, unpublished). By modeling Fall Creek watershed as a continuously stirred tank reactor (CSTR), it is possible to predict the increasing trends in salt concentrations in the watershed matching the data that was previously collected beginning in the 1970s. Based on data collected regarding quantities of salt purchased by local municipalities surrounding the watershed and inputs from wet atmospheric deposition, the model shows that the watershed system will reach steady state in approximately the year 2550 at a concentration of 35.4 ppm. Based on current conditions the salt concentration in the watershed could reach 30 ppm over the next hundred years. Harmful salt concentrations can range anywhere from 30 to 250 ppm as a conservative estimate, although accurate information in this area seems difficult to obtain. Though current concentrations in the watershed are below this range, continued monitoring of the area is important in order to supply data

that could be used to make informed decisions regarding local salt spreading policies and management techniques.

title: Microwave-Frequency Characterization of Spin Transfer and Individual Nanomagnets
abstract: This dissertation explores the interactions between spin-polarized currents and individual nanoscale magnets, focusing on the microwave-frequency magnetization dynamics these currents can excite. Our devices consist of two magnetic films (2-40 nm) separated by a nonmagnetic spacer (5-10 nm Cu or 1.25 nm MgO), patterned into a "nanopillar" of elliptical cross-section ~100 nm in diameter. One magnetic layer (a thicker or exchange-biased "fixed" layer) polarizes electron currents that then apply a spin transfer torque to the other "free" layer. We have developed several high-frequency techniques in which we excite magnetic dynamics with spin-polarized currents and detect the corresponding magnetoresistance oscillations R(t). By applying a direct current I, we can excite both small-angle and new types of large-angle spontaneous magnetic precession of the free layer, inducing a microwave voltage V(t) = IR(t) across the junction that we measure with a spectrum analyzer. By studying the linewidths of the corresponding spectral peaks as a function of bias and temperature, we find the oscillation coherence time (related to the inverse linewidth) is limited by thermal fluctuations: deflections along the precession trajectory for T < 100 K, and thermally-activated mode hopping for T > 100 K. We have also developed a new form of ferromagnetic resonance (FMR) in which we use microwave-frequency spin currents to excite dynamics, and a resonant (DC) mixing voltage to measure the response. With this technique we can directly probe the magnetic damping in both layers, identify the dynamical modes observed in the DC-driven experiment, observe phase locking with these modes, and even probe the physical form of the spin transfer torque. For metallic devices we find the torque is always confined to the plane of the layers' magnetizations, while for (MgO) tunnel junctions we find a new component of the torque perpendicular to this plane, appearing at higher bias voltages. This new FMR technique should be able to probe much smaller devices still, enabling new fundamental studies of even smaller magnetic samples, someday approaching the molecular limit.DARPA through Motorola, the Office of Naval Research, the Army Research Office, NSF (DMR-0605742),

title: ANALYSIS OF ENTRAINMENT AND CLAMPING LOSS IN AN OPTICALLY ACTUATED MEMS
abstract: This thesis presents a study of thin, planar, radio frequency MEMS resonators that are shown to self-oscillate in the absence of external forcing, when illuminated by a DC laser of sufficient amplitude. Entrainment or frequency locking is achieved in these devices when an external forcing strong enough and close in frequency to that of the unforced oscillations is applied. The forcing can be accomplished either parametrically, by modulating the laser beam incident on the oscillator, or nonparametrically, using inertial driving. The system exhibits both 2:1 and 1:1 resonances, as well as quasiperiodic motions and hysteresis. Dynamics of a three dimensional system of coupled thermo-mechanical model for the forced disc resonator is studied, using a perturbation scheme. Perturbation results show that the model agrees well with experiments and explain how and where transitions into and out of entrainment occur. Simpler canonical models showing

similar behavior are also studied. Next a method to improve Quality factor (Q) of these devices is studied. Q is a measure of damping and models the total losses in a dynamical system. As MEMS vibrates, a fraction of its vibration energy is transmitted to the substrate upon which the MEMS are fabricated. A large component of this energy is carried away as surface acoustic waves (SAW). This energy is either scattered or dissipated into the relatively infinite expanse of the substrate and termed as anchor loss in the system. A design that improves the Q of dome shaped oscillators by up to 4 by reflecting surface wave energy back to the MEMS is demonstrated. Wave reflection occurs at trenches fabricated in a circle around the MEMS. The trench creates a ?mesa? that provides partial mechanical isolation to the MEMS. Finite element analysis (FEA) is used to model these losses with infinite elements acting as quiet boundary for the truncated substrate domain. These boundaries absorb most of the outgoing energy and model the relatively infinite expanse of the substrate. The results predicted by the model agree well with the experiments and are also able to predict the experimentally observed improvement due to the presence of a mesa.CCMR, Theoretical and Applied Mechanics, Cornell University

title: SHORT-RANGE WAKEFIELD CALCULATIONS FOR THE ION CLEARING ELECTRODES IN THE CORNELL ENERGY RECOVERY LINAC
abstract: The presence of trapped ions in the Cornell Energy Recovery Linac (ERL) can lead to beam halo, particle loss, optical errors, or transverse and longitudinal instabilities. DC clearing electrodes that create a sufficient voltage to draw ions out of the beam potential are considered to be the most easily applicable measure to cure these effects. However, due to the short length of electron bunches in the ERL running modes, the power dissipated by the clearing electrodes can significantly damage these. I have calculated the short-range wakefields of different types of clearing electrodes and concluded that a tapered electrode design can be used.

title: The Effects of Ethnicity on Adolescent Resilience against Depression
abstract: Adolescents (N=6,504) from the National Longitudinal Study of Adolescent Health participated in a study exploring racial differences in access to resources against depression. Significant results indicated Black adolescents? advantage on perceived adult and family support, perceived intelligence, self-esteem, active coping skills, and college expectations; Hispanics were advantaged in maternal relationships. White adolescents? resources were parents? education, two biological parent households, two parent households, perceived peer support, and survival expectations. Hispanic and Black adolescents were more likely to be on welfare with the former also suffering through unemployment and the latter living with a single mother.

Whites were most likely to live with a single father. Future research should investigate the interactions? potency and apply it to treatment of adolescent depression.

title: Juvenile Offenders' Risky Decision-Making Behavior
abstract: We examined the choices of 52 adolescents (18 years of age); 26 were enrolled in an alternative to incarceration program and 26 were university undergraduates. Respondents were presented with a gambling task and were shown two spinners, one offering a sure gain (or loss), the second offering a gamble (probabilities of the gamble included ?, 1/3 and ?; magnitudes of the gamble included low, medium and high monetary amounts). Participants received 18 trials, nine framed as gains and nine framed as losses (each gain condition was analogous to a loss condition) and individuals were asked to report their confidence after each scenario. In the gain frame, respondents began with nothing and were offered a choice between a sure gain and a gamble offering the possibility of winning larger amounts or winning nothing. For the loss frame, individuals were given an endowment and could lose an amount for sure or take a chance and risk losing nothing or risk losing everything. In each corresponding gain and loss pair, the net sum that could be won was kept equal. In addition, respondents completed surveys on sensation seeking, behavioral inhibition and behavioral activation.
Data analysis was conducted both without and with the confidence ratings. In both regressions, delinquents scored significantly higher on sensation seeking in the gain frame, but not in the loss frame. In the first ANOVA, magnitude was a significant effect as was the interaction between magnitude and the population of the participant. Delinquents were more likely to choose the gamble regardless of the magnitude, while undergraduates picked the sure option at higher magnitudes. Also, a three way interaction was found between framing, probability and magnitude. The second ANOVA, replicated these findings and probability became a significant effect. Such results highlight the potential benefit of programs that work to enhance decision-making processes in order to prevent initial crime or potential recidivism.

title: Approximate Dynamic Programming and Stochastic Approximation Methods for Inventory Control and Revenue Management
abstract: In this thesis, we develop approximate dynamic programming and stochastic approximation methods for problems in inventory control and revenue management. A unifying feature of the methods we develop is that they exploit the underlying problem structure. By doing so, we are able to establish certain theoretical properties of our methods, make them more computationally efficient and obtain a faster rate of convergence.

In the stochastic approximation framework, we develop an algorithm for the monotone estimation problem that uses a projection operator with respect to the max norm onto the order simplex. We show the almost sure convergence of this algorithm and present applications to the Q-learning algorithm and the newsvendor problem with censored demands. Next, we consider a number of inventory control problems for which the so-called base-stock policies are known to be optimal. We propose stochastic approximation methods to compute the optimal base-stock levels. Existing methods in the literature have only local convergence guarantees. In contrast, we show that the iterates of our methods converge to base-stock levels that are globally optimal. Finally, we consider the revenue management problem of optimally allocating seats on a single flight leg to demands from multiple fare classes that arrive sequentially. We propose a stochastic approximation algorithm to compute the optimal protection levels. The novel aspect of our method is that it works with the nonsmooth version of the problem where capacity can only be allocated in integer quantities. We show that the iterates of our algorithm converge to the globally optimal protection levels.
In the approximate dynamic programming framework, we use a Lagrangian relaxation strategy to make the inventory control decisions in a distribution system consisting of multiple retailers that face random demand and a warehouse that supplies the retailers. Our method is based on relaxing the constraints that ensure the nonnegativity of the shipments to the retailers by associating Lagrange multipliers to them. We show that our method naturally provides a lower bound on the optimal objective value. Furthermore, a good set of Lagrange multipliers can be obtained by solving a convex optimization problem.

title: Developmental Changes in Infants' Knowledge of the Instrumental Value of Babbling
abstract: The present study sought to discover the age at which infants realize that their vocalizations may be used to elicit social responses from others, and to examine whether infants? knowledge of the consequences of their babbling is related to their primary caregivers? natural levels of responsiveness. Participants were 27 caregiver-infant dyads from the Ithaca, NY area. Infants were 2 and 5 months of age. Infants participated in an unstructured play session with their caregivers, followed by a still-face interaction with an unfamiliar experimenter who initially engaged the infants, and then became quiet and assumed a neutral expression. Five-month-olds exhibited a significant increase in the quantity of non-cry vocalizations from the first interaction period to the still-face, thus demonstrating that they have learned that their vocalizations have an effect on others. Two-month-olds did not show a significant change in the quantity of vocalizations. No significant relationship was found between caregiver responsiveness and infants' vocal behavior across the still face.

title: Development of Coping in Low- and Mid-Income Youth
abstract: The environment of poverty has been implicated as a major risk factor for later childhood adjustment and achievement. The present study examined the effect of exposure to poverty at age 8 on coping at age 13 using measures of coping and family income-to-needs ratio. Additionally, temperament at age 8 was examined as a potential moderator of the relationship between poverty and adolescent coping. The study hypothesized that exposure to poverty at age 8 would predict adolescent?s use of disengagement coping strategies (e.g., avoidance, distraction, or inaction). Temperament was predicted to moderate the relationship between poverty and disengagement coping strategies. Results of regression analyses indicated that exposure to poverty at age

8 predicted adolescent inaction in response to stress. Furthermore, the relationship between poverty status at age 8 and distraction at age 13 was moderated by temperament (age 8).

title: Engineering Surface Morphology at the Atomic Level with Applications in Electronic Materials
abstract: The silicon (111) and (001) surfaces have wide technological importance. Control of the morphologies of these surfaces at the atomic level is vital for such applications as layer-by-layer growth or assembly of nano-scale devices. We have developed techniques to create large areas with no or widely spaced atomic steps on patterned silicon surfaces by high temperature annealing in ultra-high vacuum (UHV).
At annealing temperatures high enough to promote surface premelting, large liquid-like structures form and are preserved during quenching on regions with low step-density since these areas have no efficient sinks to absorb diffusing atoms. Based on the surface morphologies observed by atomic force microscopy, we suggest a sequence of events for the evolution of the silicon surface, from the onset of surface premelting up to the bulk melting temperature. Large dendritic islands observed on the more slowly cooled down Si(111) samples are attributed to the persistence of surface melted structures and to non-equilibrium "condensation" of the excess adatoms from the (1x1) ? (7x7) phase transition. The effect of UHV high temperature annealing on the Si(111) surface is an initial increase in the measured surface roughness due to Ostwald ripening followed by a surface smoothing to become atomically flat. The boundaries of etched craters or mesas initially develop profiles upon annealing that conform to the predictions of continuum theory of surface transport. As an application, we built MOS capacitors on three types of Si(111) surfaces viz. atomically flat surfaces, normal (stepped) surfaces cleaned in UHV by high-temperature annealing and normal, RCA cleaned wafer surfaces. The leakage current through the oxide was measured for all three cases. Our results show that the smoother the surface before oxidation, the smaller the leakage current. In another application Si(111) substrates with regular arrays of atomic steps were used to induce azimuthal alignment of crystals in thin pentacene films. Pentacene films deposited on heated samples, at a low deposition rate, show significant azimuthal alignment of the pentacene crystals relative to the atomic steps, with the (110) pentacene planes being parallel to the atomic steps.Cornell Center for Materials Research (CCMR) grant number DMR-0079992 National Science Foundation (NSF) grant number DMR-0109641

title: Risk, Growth and Social networks
abstract: This dissertation is an empirical investigation on the microeconomics of growth, focusing on the role of shocks and on the formation of credit networks. It uses original data, collected in Southern Ethiopia, an environment where nonlinear wealth dynamics that are at the root of persistent poverty were previously identified. The first chapter briefly places this work in the wider context of the development economics literature. The second chapter explores the causal mechanisms behind the nonlinearities identified in earlier work. It focus on the role that not only climatic shocks but also ability play in shaping different accumulation patterns. It is found that herders of low ability are expected to converge to a unique dynamic equilibrium at a small herd size, while those with higher ability exhibit multiple stable dynamic wealth equilibria. The third chapter of this dissertation validates a new approach to the collection of data on social relations that starts with a random sample of individuals and then randomly samples from the prospective relationships among sample respondents. Using original data from southern Ethiopia it is shown that this method yields estimates of the

structure of social relations that are statistically indistinguishable from those generated by tracing respondents' local networks. Through the use of Monte Carlo simulation, it is also shown that introducing this second level of sampling improves the accuracy of the inference on the determinants of network formation. The last chapter explores the effect of herd dynamics on the formation of credit networks. It finds that the threshold at which wealth dynamics bifurcate serves as a focal point at which credit transfers are concentrated and that asset loans respond to recipients' losses as long as the recipients are not "too poor". These results suggest that, when shocks can have long term effects, asset transfers may aim to insure the permanent component of income generation, rather than the transitory component, as it is commonly assumed. The chapter also shows that the persistently poor are less likely to be known within their communities and less likely to receive transfers in response to shocks.Portuguese Fulbright Commission, Fundacao Calouste Gulbenkian, Fundacao Luso-Americana para o Desenvolvimento, Fundacao para a Ciencia e Tecnologia, Social Science Research Council's Program in Applied Economics on Risk and Development (through a grant from the John D. and Catherine T. title: ETHNOPOLITICAL DEMOGRAPHICS, IDENTITIES AND THE UTILITY OF LINGUSTIC DISTANCE IN MEASURING DIMENSIONS OF COLLECTIVE GROUP CHANGE
abstract: Ethnic distance is a theoretical concept that is prevalent within political science and political economy as a metric in calculating group heterogeneity but has been difficult to apply in terms of making actual empirical measurements. Ethnic distance can be considered in two related ways. The first can be conceived as the relative variation within and between specific ethnic populations in social or geographic space and supervenes on the individual in the costs of identifying ethnic in-group members from out-group members. The most widely used metric in the literature is language which is made more complex in that there are multiple level differentiating linguistic forms and criteria for measurement. I suggest the development of a measure of linguistic distance that uses the Levenshtein algorithm to produce a numeric value of pronunciation distance by calculating the number of changes that is needed to transform one linguistic string into another. As this value is numeric it can be applied to statistical measures measuring linguistic heterogeneity at the population level and is sensitive enough to detect dialectical differences and can be applied to experimental work on the ethnic identification or location of individuals within a particular language community.

title: CONMan: A Step towards Network Manageability
abstract: Networks are hard to manage and in spite of all the so called holistic management packages, things are getting worse. Further, there is a general lack of research on fundamentals and an increasing reliance on temporary "bandaids". We argue that the difficulty of network management can partly be attributed to a fundamental flaw in the existing architecture: protocols expose all their internal details and hence, the complexity of the ever-evolving data plane encumbers the management plane. Guided by this observation, in this paper we explore an alternative approach and propose Complexity Oblivious Network Management (CONMan), a network architecture in which the management interface of data-plane protocols includes minimal protocol-specific information. This restricts the operational complexity of protocols to their implementation and allows the management plane to achieve high level policies in a structured fashion. Apart from building the CONMan interface of a few protocols and a management tool that can achieve high-level configuration goals based on this interface, our preliminary experience with applying this tool to real world VPN configuration indicates the architecture?s potential to alleviate the difficulty of network management.

title: Reflections of a Military Medium: Ritual and Magic in Eleventh and Twelfth Century Chinese Military Manuals
abstract: REFLECTIONS OF A MILITARY MEDIUM: RITUAL AND MAGIC IN ELEVENTH AND TWELFTH CENTURY CHINESE MILITARY MANUALS
Marcia Butler, Ph. D.
Cornell University 2007
This dissertation considers ritual documented in comprehensive military manuals--a genre that fully emerged during Song dynasty China (960-1279 AD)--and its role in Song cultural and intellectual history. These manuals represent the earliest documentation of such rituals, and include prayer texts, instructions for sacrifice, moral admonitions, war initiation and conclusion rites, reading the ether, and sorcery techniques. The Song military system provides a good case study for determining specific beliefs and how those spread because of the nature and function of the system; its social composition, collective potential, inherently violent motivation, mobility, and organization. The study makes the case that rituals in these manuals, which many scholars have dismissed as irrelevant to the Song military project, were an integral part of Song warfare. Such rituals reveal syncretic systems of thought and belief practiced during the Song. Using 'magic' and occult rituals, the study explores the production of social collectivities within the Song military and shows how specific rituals produced various sorts of power. Among the latter, the universal force of yin, not yang (as might be expected), was the domain for production of power. I augment the prescriptive texts of the manuals with descriptive sources--encyclopedia, official histories, battle diaries and anecdotal accounts--to determine actual performances, both within the military and at court. These rituals provided sites of contention and comprised an arena for discourse between the groups that made up the military and the imperial court. With respect to the latter, the study investigates the dynamic of the supposed separation between the civil (wen) and the martial (wu), commonly attributed to the Song, and finds that the separation was not as definitive or unambiguous as is commonly portrayed. Finally, detailed analysis of various rituals shows that they were based on visual representations (xiang) that figured largely in competing Song cosmological schema. As these representations detached from their originating text, they were ritually transformed and then incorporated as cultural and supernatural emblems that mimicked natural forces and became themselves objects for

manipulation and sources for the production of power.

title: Profit Priorities and Cost Distribution: Sociocultural and ecological impacts of Chilean forest management
abstract: Questions: What does the government prioritize when facing conflicting social, environmental and economic demands? What are the impacts and how can these demands be balanced in a responsible, progressive and humanitarian way?
This research uses a political ecology framework to discuss the sociocultural, economic and environmental implications of Chilean forest management practices. This is a critical analysis of the Chilean government?s priorities, which currently promote an extractive export economy at high social and environmental costs. Despite a growing economy, the wealth disparity in the country is vast and continues to expand. I argue that the government must reorient its focus away from GDP and toward more valuable measures of the country?s health. Public funds need to be redistributed to benefit the people in the country and the country?s natural treasures rather than subsidizing private industry to attract wealthy foreign investors. This shift in priorities must be implemented in strong, creative policy that supports simultaneous economic growth, environmental preservation, and social justice.
This project is based on personal experiences, interviews and observations from when I lived in Chile during the spring of 2006, as well as on secondary sources that provide scientific and statistical evidence. I describe the history of the forest plantation development, the government?s role in creating the industry that exists today, and current statistics that show the scope and significance of the industry. Different sources present conflicting evidence depending on their interests, demonstrating the complexity of the controversies around the social and ecological impacts of the forest plantations. Various avenues for change are possible: policy restructuring, market control methods, improved ecological management, and social and environmental activism promoting government and citizen awareness and responsibility. Government leaders are integral to promoting human rights and environmental preservation and it is their responsibility to prioritize these goals at least as much as private investment.

title: Precession of Neutron Stars
abstract: We model long term variations detected in the period residuals of pulsar PSR B1828-11 in terms of precession of an asymmetric rigid body. We consider two contributions: the geometric effect, due to variation of the pulsar beam orientation with respect to the observer with precession phase; and the spindown contribution, due to dependence of the spindown torque on the angle between the rotation and magnetic axes. We use the data to probe various properties of the star, most notably its shape. We find that a wide range of models are able to explain the variations in terms of precession. We offer an explanation for the observed variations in the pulse shape in terms of a compound beam structure.
Neutron stars will be deformed by their magnetic fields, which can explain long term variations in their period residuals. Magnetic stresses in normal conductors are insufficient (by a factor of about a thousand) to account for the deformation inferred for PSR B1828-11. However, magnetic stresses in type II superconductors (which form in neutron stars) can produce the necessary deformation.
We determine the form of axisymmetric toroidal magnetic fields in completely fluid, non-rotating, type II

superconducting neutron stars, consistent with magnetohydrostatic equilibrium and boundary conditions. Using Lagrangian perturbation theory we determine stellar deformations for various models of neutron stars with type II superconducting and normal regions. We find that the star becomes prolate and can be sufficiently distorted to display precession with a period of the order of a few years.
We also study the stability of toroidal fields using an energy principle and a local analysis. We extend the stability criteria established by Tayler for normal conductors to include type II superconductors with magnetic free energy that depends on density and magnetic induction. We also derive the conditions and growth rate for a specific instability of type II superconductors, first discussed by Muzikar, Pethick and Roberts.
Finally, we consider the harder problem of poloidal fields in type II superconductors. In this case, the magnetic field direction, as well as strength, is unknown, and needs to be calculated numerically.

title: False Recall in Manipulations of the DRM Paradigm
abstract: Senior Honors Thesis 2007 - Department of Human Development, Cornell UniversityThis study was conducted using the DRM paradigm to try to further comprehend false recall positioning. The objective of this study was twofold: to demonstrate that gist, verbatim, and gist + verbatim instructions can alter the positional output of true versus false memories, and to see whether placement of these memories can be affected by other manipulations and their interactions. Results showed that altering the instructions given has a statistically significant effect (at the p <.000 level) in regards to the placement of false memory and true memory,. Significant effects were also witnessed for various other manipulations that confirm the dual process theory. Although the study presented limitations, the results are very useful when applied to criminal investigations and psychotherapy.

title: DYNAMIC SILICON NANOPHOTONIC DEVICES
abstract: This dissertation is driven by a vision to continue improvements in system functionality by alleviating bottlenecks in interconnects and enabling the processing of large amounts of information on a chip. Light was the key for achieving long-haul interconnects 35 years ago and is now becoming the key for achieving high speed data communications on smaller scales [1-3]. The ultimate goal of this research is continue this trend to the smallest possible scale by developing a complex integrated Silicon Nanophotonic chip. Here I will present some of the building blocks for such a chip.
This dissertation is divided in five chapters, organized as follows. Chapter 1 gives an overview of why optical interconnects are needed on the chip scale. Then it discusses the challenges and the advantages of using a Silicon platform for such a photonic chip. We then provide a solution to the challenges by using compact resonators to dramatically increase light-matter interaction.
In Chapter 2 we demonstrate one of the most basic building blocks of a silicon nanophotonic chip ? an all-optical modulator, where one beam of light controls the propagation of another. First we present low-powered all-optical modulation using a one-dimensional photonic crystal nanocavity. Then we demonstrate ultra-fast modulation using a ring resonator device with an integrated PIN diode. The diode is used to dramatically increase the speed of typical silicon modulators to at least 20 Gbit/s.
In Chapter 3 we discuss using evolutionary algorithms to design silicon nanophotonic devices that outperform human designs. In order to demonstrate the promise of evolutionary algorithms we present an example that designs a photonic crystal with a bandgap that is larger than previous human designs.
In Chapter 4 we present a new technique for achieving wavelength conversion where the wavelength of light confined in a resonator is changed by dynamically tuning the resonator. We discuss theoretically how this occurs and then demonstrate it experimentally using a ring resonator device.
Finally in Chapter 5, we demonstrate photonic transitions where light is transitioned between the discrete states of a resonator, in analogy to electronic transitions in an atom.

title: Essays on Model Selection
abstract: Model selection and nonnested hypothesis testing procedures are considered in three papers. The papers generalize the existing testing procedures and propose methods to improve approximations to the sampling distribution of the test statistics. The first paper proposes robust tests which generalizes the J test (Davidson and MacKinnon (1981)) and the F test (Deaton (1982) and Dastoor (1983)) for non-nested dynamic models with unknown serial correlation and conditional heteroskedasticity in errors. In the second paper, a model selection procedure based on a general criterion function, with an example of the Kullback-Leibler Information Criterion (KLIC) using quasi-likelihood functions, is considered for dynamic non-nested models. I propose a robust test which generalizes Lien and Vuong's (1987) test with a Heteroskedasticity/Autocorrelation Consistent (HAC) variance estimator. In both papers, I use the fixed-b asymptotics developed in Kiefer and Vogelsang (2005) to improve the asymptotic approximation to the sampling distributions of the test statistics. The fixed-b approach is compared with a bootstrap method and the standard normal approximation in Monte Carlo simulations.

The third chapter considers the nonnested hypothesis testing of Vuong (1989) for which the null hypothesis is that the candidate models are equidistant in KLIC from an unknown true model. I propose a higher order asymptotic bias correction of the test statistic and show that it is invariant with respect to reparameterization. The reparameterization invariance leads to the differential geometrical approach where coordinate system invariant quantities like curvature are useful for understanding the corrections. The relationship of the correction factor with the preferred point geometry of Critchley et al. (1993, 1994) and the expected geometry of Amari (1982) is illustrated.

title: Generalized Wavelet Thresholding: Estimation and Hypothesis Testing with Applications to Array Comparative Genomic Hybridization
abstract: Wavelets have gained considerable popularity within the statistical arena in the context of nonparametric regression. When modeling data of the form y = f + \epsilon, the objective is to estimate the unknown `true' function f with small risk, based on sampled data y contaminated with random (usually Gaussian) noise \epsilon. Wavelet shrinkage and thresholding techniques have proved to be quite effective in recovering the true function f, particularly when f is spatially inhomogeneous.
Recently, Johnstone and Silverman (2005b) proposed using empirical Bayes methods for level-dependent threshold selection in wavelet shrinkage. Using the posterior median estimator, their approach amounts to a random thresholding procedure with impressive mean squared error (MSE) results. At each level, their approach considers a two-component mixture prior for each of the wavelet coefficients independently. This mixture prior inherently assumes that the wavelet coefficients are symmetrically distributed about zero.
Depending on the choice of wavelet filter and the interesting attributes of the true function, it may be the case that neither the magnitude nor the number of positive coefficients are equal to the those of the negative coefficients. Inspired by the work of Zhang (2005) and Zhang et al. (2007), this thesis introduces a random generalized thresholding procedure in the wavelet domain that does not require the symmetry assumption; it uses a three-component mixture prior that handles the positive and negative coefficients separately.
It is demonstrated that the proposed generalized wavelet thresholding procedure performs quite well when estimating f from a single sampled realization y. As in Johnstone and Silverman (2005b), the performance of the Maximal Overlap Discrete Wavelet Transform (MODWT) is substantially better than that of the standard Discrete Wavelet Transform (DWT) in terms of MSE and visual quality. An additional advantage for MODWT is that it is well-defined for any number of sampled points N, i.e., N need not be a power of two. The proposed procedure also performs well when estimating f from multiple noisy realizations y_i, i = 1,...,n.
In most, if not all, of the shrinkage and generalized shrinkage techniques considered, the noise standard deviation is assumed to be known and constant across the length of the function. In reality, it is typically not known and must be estimated. In the single realization setting, the estimate is usually taken to be a constant based on the median absolute deviation of the empirical wavelet coefficients at the finest decomposition level. With multiple realizations, there are more estimation options available. Various estimation options for a constant variance are examined via simulation. The results indicate that three of the six estimates considered are reasonable choices. The case of heterogeneous variances across the length of the function is also briefly explored via simulation.
Finally, an inferential procedure is proposed that first removes noise from individual observations via the generalized wavelet thresholding procedure, and then uses newly proposed F-like statistics (Cui et al., 2005; Hwang and Liu, 2006; Zhou, 2007) to compare populations of sampled observations. To demonstrate its applicability, the aforementioned statistical work is applied to datasets generated from Array Comparative Genomic Hybridization (aCGH) experiments.

title: Strategic Networking in Standard Setting Organizations: The Case of JEDEC
abstract: This paper examines the strategic impact of networking within a cooperative standard-setting body. The JEDEC JC-42 committee sets standards for memory technologies, and was especially focused on DRAM standards in the early 1990s. I utilize cross-sectional and panel data to analyze whether internal networking helped firms to exert an influence on the development of formal standards for memory technology in general and DRAM technology in particular. Cross-sectional and panel results tentatively suggest that networking within JEDEC, in terms of attendance at different subcommittee meetings, contributed to firm influence on standards development. A somewhat surprising result, given industry-wide concern about DRAM standards, is that non-DRAM-related networking and standard setting activity proved more important for overall standards development success. In addition, coefficients on variables measuring intellectual property holdings suggest that IP portfolio tends to hurt firms in the standard setting process.
Interpretation of results should bear in mind small sample size and limited panel variation, which may yield inconsistent estimators of coefficients. Moreover, although I emphasize results in random effects models because they reflect more observations, fixed effects may be more appropriate given that firm-level characteristics underlie fixed and random effects. In conclusion, cross-sectional and panel analyses tentatively suggest that internal networking contributed to firm influence on standards development within the JEDEC JC-42 committee in the early 1990s. But further study using a richer dataset and accounting for institutional anomalies could improve our understanding of the strategic value of networking, both within and outside JEDEC, in the effort to develop next-generation DRAM standards.

title: TURKISH ISLAMIC CLAIMS MAKING IN GERMANY: MILLI GORUS IN BETWEEN LOCAL AND GLOBAL
abstract: Recent academic work on the powers of the nation state has argued that nation state's position as the predominant unit of social organization is being diminished from outside by forces of globalization and through the shift of power from the national to the supra and transnational levels. It is also argued that the nation state's legitimacy, authority and integrative capacities are weakened form within by an increasing number of claims for special group rights emphasizing cultural difference. Not surprisingly, migrants and

ethnic minorities have been at the forefront of these claims; arguably contributing through their claims making both to the external erosion of sovereignty and to internal cultural differentiation. Post-nationalists argue that citizenship and welfare rights possessed and otherwise demanded by non-citizens contribute to the erosion and transcending of the frontiers of nation-states while migrant communities increasingly take on the character of transnational communities taking advantage of transnational political opportunities. Multiculturalists, in turn, argue that the liberal nation state is challenged when migrant minorities question the conception of a unified undifferentiated citizenship by putting forward demands for special group rights and for the recognition of cultural difference. A third strand of thought has emerged in response to these claims from supra-nationalists and multiculturalists emphasizing the continuing importance of the nation-state particularly in shaping migrant experience in general and migrant claims making in particular. Scholars have analyzed the citizenship configurations of nation-states as the explanatory variable in explaining different strategies in dealing with ethnic difference and the different manifestations of these strategies in different countries. In contrast to the above summarized polemical opposition of nation-state bound approaches on the one hand and an unbounded supra-nationalism on the other, I argue that host/home country influences, extra nation-state influences and group ideological/religious orientations affect migrant claims making through mechanisms like attribution of opportunity or threat and internalization. To specify the role of these factors in influencing migrant claims making and the inner workings of these mechanisms, I analyzed Milli Gorus Germany claims through content analyses of organizational media and observed changes and trends in the nature of this claims making. I also documented Milli Gorus Germany's organizational ties and conducted open-ended interviews with organization members to understand what factors have influenced these trends and changes. My findings show that understanding migrant claims making necessitates long term case study analyses of the claims making strategies of particular migrant groups. While national citizenship models do have an influence on the nature of migrant claims making in a particular country, claims making strategies of migrant groups are also influenced by home country, supra/transnational and intra-group changes. First, my empirical analysis shows that Milli Gorus Germany claims emerge as an outcome of broad change processes (national or international) which are attributed as threats and opportunities depending on the ideological/religious identification of group. Second, I show that extra-nation state pressures and events can unexpectedly lead to a very domesticated claims making due to internalization which I claim is dependant on an already emerging host-country orientation within the immigrant group. I argue that my focus on dynamic processes and mechanisms linking the local and global not only helps us to trace and explain changes in the nature of Milli Gorus Germany claims making over time, but it also enables us to understand the interaction of the local and the global. The global doesn't always rule the local and the local doesn't always rule the global. They interact in previously undetermined ways to affect migrant claims making through processes like attribution of threat and opportunity and internalization and create different claims making strategies over time and between different groups.

title: SYNTHESIS OF A STRUCTURALLY AND STEREOCHEMICALLY DIVERSE SPIROKETAL LIBRARY USING NOVEL STEREOSELECTIVE SPIROCYCLIZATIONS OF C1-SUBSTITUTED GLYCAL EPOXIDES
abstract: A chemical genetic approach that uses small organic molecules to modulate protein function has the potential to overcome the limitations of classical genetic techniques for the study of biological processes. However, acquiring the features of broad applicability and specificity that are inherent to traditional genetics is still a challenge in chemical genetics. The impact that chemical genetics will have on our understanding of biological systems depends on a steady supply of biologically active small molecules with novel targets or

improved specificity for known targets.
Diversity-oriented synthesis (DOS) of small molecule libraries is an emerging method to identify new probes for biological studies and potential therapeutic lead compounds. We have explored the use of an approach that employs structural features commonly found in natural products as starting points for library design. Our library incorporates spiroketal motifs, but is otherwise stereochemically and structurally diverse to address a wide range of biological targets. Although many efforts have been made to synthesize members of the spiroketal class of natural products, traditional methods are not suitable for generating stereochemical diversity in DOS. Therefore, we have developed a strategy to create stereochemical diversity by using novel stereocontrolled spiroketalization reactions that provide access to both spiroketal stereoisomers from a common C1-substituted glycal epoxide precursor. Our route has allowed the synthesis of a library of diastereomeric spiroketals in which we control the stereochemical configuration not only at the quaternary spiroketal carbon, but also at multiple ring carbons. The library will ultimately be screened against a number of biological targets to evaluate the effectiveness of the design strategy, and potentially identify new biological probes or lead compounds for drug development.

title: Science About What Scientists Do: Distinguishing Between Explanations for Causal Events
abstract: The causal reasoning literature suggests that hypothesis testing will only include tests that support a particular hypothesis (confirmation bias), rather than distinguish between possible hypotheses (Wason,

1960; Mynatt, Daugherty, & Tweney, 1977; Klayman & Ha, 1987). Self-generated hypotheses should elicit a stronger confirmation bias than other-generated hypotheses, possibly because the generation of a hypothesis requires an initial assessment of plausibility (Schunn & Klahr, 1993). Plausibility is determined by considering a possible cause within a network of prior knowledge about the world (Koslowski, 1996). Our study examines the testing of genuine explanations in non-emotion-laden, complex causal reasoning situations. We predict that the source of the explanation (self or other) and presence of alternative explanations will influence ability to distinguish between two hypotheses. Furthermore, we predict that the incorporation of prior knowledge into the hypothesis test will allow individuals to distinguish more successfully. Sixty subjects (F = 32, aged 18-22) completed a structured interview evaluating explanations that varied on number of explanations present and source of explanation. Ability to distinguish between a target explanation and its complement (but not a genuine alternative) was shown to differ based on the source (self or other) of the target and whether an alternative was provided. Prior knowledge was only used when distinguishing between the target and a genuine alternative. In general, the use of a contrast or covariation test is the best predictor of ability to distinguish between two explanations.

title: Keeping Stolen Land
abstract: This thesis explores the common roots of several contemporary social movements in Durban, South Africa. My point of departure is a series of community meetings in May, June, and July 2006, during which geographically separated Black and Indian community organizations expressed remarkably similar grievances against the municipality and government, all rooted, I argue, in the colonial dispossession and alienation of Africans, and later in the enforced marginalization of Indian communities. Largely, these dispossessions occurred in the 19th century and early in the 20th century ? decades before the policy Apartheid begin in 1948. It is the continued relationship of exclusion and repression in relation to land and space in Natal, I argue, that accounts for the common struggles of these movements. I shall cite Antonio Gramsci extensively in order to argue that his conceptions of ?consent? and ?coercion? explain the perpetual success of policies designed to preserve colonial and Apartheid dispossession. Moreover, several labor struggles will be considered in order to illustrate the degree to which the majority?s consent has been secured, and to offer evidence that Gramsci?s theories are powerful assistance to us. Moreover, Mahmood Mamdani?s identification of ?subject? and ?citizen? will factor, as the transition from Apartheid to ANC rule has essentially cemented the status of landless South African subjects. His lengthy iteration of indirect rule in Apartheid South Africa will become crucial to understanding how the transition was ineffectual for many.
In addition, by surveying documents relating to the management and control of these populations, I argue that (KwaZulu-)Natal?s managers, through several succeeding governing regimes, have implemented policies of great similarity to achieve the same effect ? keeping the power of land and space of Natal in the hands of Europeans. These movements represent, I believe, an iteration of a continued resistance to policies of exclusion from and access to valuable land and space in the province. From their concerns and mobilizations, I will finally attempt to construct an understanding of what has, and has not, changed in South Africa.

title: Decolonizing Mimesis in the Works of Jessie Fauset, David Bradley, and Nelly Rosario
abstract: DECOLONIZING MIMESIS IN THE WORKS OF JESSIE FAUSET, DAVID BRADLEY, AND NELLY ROSARIO
Victoria Alicia Chevalier, Ph.D.
Cornell University, 2007
Decolonizing Mimesis in the Works of Jessie Fauset, David Bradley, and Nelly Rosario historicizes the category of mimesis by tracing its function as a modality in 20th Century African American Literature. Decolonizing Mimesis interprets the modalities of mimesis across disciplinary schools of thought as a historicized literary function, not a trans-historical category. For this reason, in different historical contexts in African American literature, mimesis takes on different possibilities for the black subject of language in a decolonizing frame. The works upon which I focus engage what occurs when the problem of mimesis as a category of interpretation presses up against the problem of African American representation. Jessie Fauset?s Plum Bun and The Chinaberry Tree, David Bradley?s The Chaneysville Incident, and Nelly Rosario?s Song of the Water Saints engage the ways in which black subjects in representation destabilize the logic of identity as irreducible difference that underpins scientific racism and racist practices in America, and through contact with America; simultaneously, these works insist upon an understanding of a shared vernacular, because inherited history constitutive of ?race? through the attainment of a decolonizing and, therefore, oppositional position within discourse. This position within language is specifically rendered through the literary tropes ellipsis, caesura, and aporia. These tropes are themselves figures for a blank space, a silence, or a pause whose presence in these texts is visible and invisible, legible and illegible. Decolonizing Mimesis argues that the transformative work of identification, as opposed to identity, is the primary project with which the aspects of the interior world are represented throughout these texts. In an attempt to stave off the putative annihilation of racial uplift, these works argue for a black world in which play is possible, indeed necessary, for decolonizing representational properties acquired by black subjects. Although the early chapters of the dissertation focus on the literary project of the Harlem Renaissance as it is understood by Jessie Fauset, I pay attention throughout to the way the novels are concerned with modalities of mimesis expressed in psychoanalytic, narrative, and aesthetic paradigms, particularly regarding the ritualization of history and memory. I demonstrate, for instance, that Fauset?s work relies on figures of visuality and visual technologies to organize modern identification rituals and subject-formation established in psychoanalysis; Nelly Rosario?s work constitutes the limits of a nascent and oppositional Caribbean historical narrative represented by the discontinuities of an alternative and black postmodernity; and both confront history through visual and narrative mimetic models that necessarily fail to inscribe a black feminine subject across the fallacy of binaries ?self/other,? ?masculine/feminine,? ?white/black.? Finally, my chapter on David Bradley?s The Chaneysville Incident argues that this text participates in a similar logic which motivates Fauset?s and Rosario?s work. A potential alternative sexuality, and therefore a different relation to memory and history link Bradley?s work to Fauset and Rosario?s representation of repressed, black subjects. The novels I focus upon in this dissertation argue that history inevitably brings itself to bear; therefore the only way to effect literary and social change is through praxis, through a confrontation with linguistic and figurative historical forms, themselves inherently political.

title: FLOCK THEORY: COOPERATION AND DECENTRALIZATION IN COMMUNICATION NETWORKS
abstract: Research has shown that decentralized organizations and groups perform better and have more satisfied members than centralized ones. Further, decentralized self-organizing groups are particularly superior when solving complex problems. Despite mounting research in support of decentralization, the means of how to foster and maintain a decentralized, coordinated group remains a particular problem for organizations. The current line of research proposes a theory of decentralized organizational communication, flock theory, and conducts preliminary tests of the theory. Grounded in literature from social networks, flock theory represents a theoretical model for the decentralized evolution of communicative systems. The flock model is then extended to integrate roadmap based flocking, bipartite networks, and findings from small world research to create a theory of cooperation, coordination, and navigation within decentralized communication networks. Empirical illustrations of flock theory are conducted via two studies on two different research-based organizations, as research organizations focus on complex problem solving and coordination of knowledge. Findings provide initial support for flock theory, confirm parallel research on decentralization, and indicate that research-based organizations may be different from traditional corporate organizations in several ways.

title: Rx-to-OTC Switch: Changes in Physician and Patient Behavior
abstract: RX-TO-OTC SWITCH: CHANGES IN PHYSICIAN AND PATIENT BEHAVIOR
Sarah Hoda Neyaz, Ph. D.
Cornell University 2007
When Claritin (a popular allergy/antihistamine drug) and Prilosec (a popular anti-ulcer/anti-acid drug) became available over the counter (OTC), a unique situation was created in which a drug was now available OTC while close substitutes remained prescription (Rx) only. The OTC/Rx status of a drug should not affect physician recommendations for it or others in its class as no chemical change has occurred. The theory developed here to model physician incentives suggests, however, that due to several institutional features of insurance markets, such as reimbursement methods, there may be differences in the incentives faced by physicians that lead to changes in which medications are prescribed as drugs switch regulatory status. In this model, capitated physicians are expected to use the lowest cost form of treatment since they can be held financially responsible for their treatment decisions. The existence of an OTC version of a drug is also hypothesized to alter patient behavior as well. The availability of an OTC is expected to increase the likelihood that patients will self-medicate and therefore should result in fewer visits to physicians with diagnoses related to that condition. Self-treatment with OTC drugs is likely to be greater when symptoms are not very severe. Consequently, it is also hypothesized that after the OTC drug is available those who do see a physician will manifest more severe symptoms. To test the theory empirically the National Ambulatory Medical Survey for the years 1997-2004 is utilized. The analysis shows that when a drug in a class becomes available in the OTC market, fewer patients visit physicians for the related diagnoses and the severity of ailments of patients visiting physicians does seem to change somewhat after the availability of OTC medication. There is some evidence that physicians change their prescribing behavior, when a drug moves from prescription to OTC. In both the allergy and acid reflux markets, capitated physicians are found to utilize the least costly form of treatment. These physicians are found to cost shift away from the insurance company, while FFS cost shift away from the patient. Finally, both the allergy and acid reflux classes show some evidence of brand loyalty

for drugs amongst patients.

title: ONE WAY FANOVA USING PENALIZED SPLINES
abstract: There are several methods available for smoothing scatter-plots. One interesting method involves using mixed model techniques that can be shown to be equivalent to the penalized splines method. In order to analyze certain functional data sets, we propose an extension of this mixed model approach that involves the smoothing of several scatter-plots simultaneously. More precisely, we show how one can estimate the mean profiles of functional data that have one grouping factor by fitting a single mixed model. The underlying mixed model will then be used to set up a hypotheses testing scheme for doing one way functional analysis of variance, FANOVA. In doing so, we will establish an interesting connection between the one way FANOVA problem and the problem of testing whether variance components from certain mixed models are zero. Finally we will propose a method for doing multiple comparisons in the functional setting, again using the underlying mixed model from the fitting criteria. The proposed methods are then demonstrated through an analysis of a typical functional data set.

title: Variations in sediment sources and yields in the Finger Lakes and Catskills regions of New York
abstract: The proportional contributions of stream bank and surface sources to fine sediment loads in watersheds in New York State were quantified with uncertainty analysis. Eroding streamside glacial drift, including glaciolacustrine deposits, were examined to help explain variations in the proportional contributions made by bank erosion. Sediment sources were quantified by comparing concentrations of the bomb-derived radionuclide 137Cs in fluvial sediment with sediment from potential source areas such as agricultural soils, forest soils and stream banks.
To compare sediment sources in streams containing abundant deposits of fine-grained glacial drift with watersheds that lacked moderate or extensive streamside deposits, samples were taken from 15 watersheds in the region. The mean contribution of bank erosion to sediment loads in the six streams with glaciolacustrine deposits was 60% (range 46?76%). The proportional contribution of bank erosion was also important in one stream lacking glaciolacustrine deposits (57%) but was less important in the remainder, with contributions ranging from 0 to 46%. Data from this study on the varying contributions of bank erosion and data from past studies of sediment yield in 15 watersheds of New York State suggest that eroding streamside glacial deposits dominate sediment yield in many watersheds. In other watersheds, past impacts to streams, such as channelization, have also resulted in high levels of bank erosion.

title: Rational Reconstructions of Society
abstract: The dissertation contains four stand-alone studies, chapters 2 through 5. In chapter 1, I highlight commonalities among the studies.
In chapter 2, I consider the principle of structural balance - "The friend of a friend is a friend, the enemy of a friend is an enemy, the friend of an enemy is an enemy, and the enemy of an enemy is a friend." I consider Harary's (1954) result that this principle can only be satisfied in a world consisting of two inimical friendship cliques. And I consider recent studies that show that when individuals in a structurally imbalanced world change ties one by one following the principle, they do not necessarily end up in a structurally balanced world. I prove that if multiple ties can be changed simultaneously, then a structurally balanced world is guaranteed.
In chapter 3, I consider Burt's (1992) argument of "structural holes" that unconnected parts of a social network are niches for brokerage. I consider Burt's suggestion that those aware of brokerage benefits end up occupying structurally advantaged network positions. I show how this statement crucially depends on the unawareness of these benefits by others. If everyone strives for structural holes, no one ends up with a structural advantage.
In chapter 4, I consider the extensive laboratory evidence on the relationship between the structure of small exchange networks and expected exchange rates. I consider a theory that reasonably predicts this relationship in a handful of networks. I show that if individuals add ties that increase expected earnings from exchange more than they cost and delete all other ties, then networks emerge that distribute exchange benefits equally.
In chapter 5, I consider the old immigrant assimilation model of a monotonic process. I consider recent work in the direction of an alternative model. I propose an alternative model that follows up on this work and adds minimal complexity to the old model. In this model, quite assimilated migrants further assimilate, while not so assimilated migrants reverse-assimilate. Using longitudinal survey data, I show that the model is empirically competitive.
In chapter 6, I propose four follow-up studies.

title: Narrative Skills as a Predictor of Suggestibility and Memory Accuracy
abstract: Narrative skills have been identified as an important contributor to memory development in young children. In the present research, I examine the relationship between children?s narrative skills and suggestibility as well as memory accuracy. Across two studies, a total of 112 preschool-aged children engaged in a staged event with a classroom visitor and were subsequently questioned suggestively. Results from Study 1 indicated that children's ability to provide a high quality narrative of the event was related to resistance to suggestive questions, appearing to supersede age as a predictor. Study 2 further examined the role of children's general language abilities (measured through a teacher report) and general narrative skills (measured through an autobiographical memory narrative). These results replicated the findings that children's ability to produce a high quality narrative of a previously experienced past event independently predicts resistance to suggestion independent of language skill. However, the quality of children's autobiographical memory narratives predicted increased suggestibility. In addition, in both studies high quality narratives were related to reporting more spontaneous errors. Findings are considered in light of narrative's role in memory development and underlying mechanisms which may explain children's suggestibility.American

title: SPAIN IS ILL! SICK BODY AND POLITICAL DISCOURSE IN TWENTIETH-CENTURY SPAIN: SANTIAGO RAMON Y CAJAL, PIO BAROJA, GREGORIO MARANON, AND ANTONIO VALLEJO NAGERA
abstract: In this dissertation, I study the metaphorical representations of disease by four Spanish physician writers from 1885 to 1960: Santiago Ramon y Cajal (1852-1934), Pio Baroja (1872-1956), Gregorio Maranon (1887-1960), and Antonio Vallejo Nagera (1889-1960). I analyze the role of physicians as writers and as intellectuals in Spanish peninsular literature, and I illustrate not only how they use science and medicine to define and critique nation, nationalism, culture, and politics in Spain, but also how politics can be read in these four physicians? literary production, by analyzing the metaphors of science, medicine, doctor, patient, sickness, and cure. Physician writers produce a space for social and political critique in which medical discourse becomes political discourse. Through the four chapters of my dissertation, I show that Spanish nationalism imposes a centralistic, homogeneous, and unified vision of Spain. This homogeneity leads to the construction of a Spanish nation in which the particularities of three historical nations (Catalonia, Galicia, and Basque Country) are ignored, and imposes Castilian culture in order to legitimize such a construction. Ramon y Cajal, Baroja, Maranon, and Vallejo Nagera construct a singular Spanish national culture by using the metaphor of the sick body as an opposition to the ideal healthy body, defining Spanish national culture in opposition to the other nations that constitute Spain. In order for these physicians to talk about the sick body, they refer to the Other: Americans, Catalans, Basques, intersexuals, homosexuals, Communists, and Marxists, among others. I also show that the fictionalization of the pathological body and the symbolic representation of sickness underscore these physician writers? political anxieties. Not only do these authors reproduce the ideology of the hegemonic group, but they also produce this ideology by building it from within the State, where medical discourse is institutionalized. They support an authoritarian, colonialist, imperialist, and totalitarian political regime, representing Castilian values. The literary production of these four physician writers requires a reconsideration of the cultural dynamics created by medical language, the human body, and political discourse.

title: Threat and Bias: Understanding the Role of Threat in Attitudes towards Race, Gender, and Sexual Orientation
abstract: This research project is motivated by the question of what type of relationship exists between threat

and bias. Such a relationship has been demonstrated for racial bias and theorized for sexism and heterosexism; however the nature of the relationship is unknown. In particular, it is unclear whether threat functions at the individual level, group level, or both levels simultaneously. This is accomplished by considering three types of bias: sexism, racism, and heterosexism.
All three analyses utilize virtually identical background measures and employ ordered logistic and multinomial logistic regressions, with differing outcome measures and threats. Each paper begins by considering how the relevant literatures treat threat and bias. They then examine the same four hypotheses describing the possible relationships between individual threat, group threat, and biased attitudes.
The gender and race analyses utilize the General Social Survey. Attitudes towards policies aimed at promoting gender equity are the outcome measures for the gender study, while attitudes towards policies aimed at promoting racial equity are the outcome measures for the race analysis. Threat measures assess perceptions of the impact of the women?s movement on individuals and men (gender analysis) and perceptions of white job security and stability (race analysis).
The sexual orientation analysis relies on student data, because there are no available datasets with appropriate measures of individual and group threats. A questionnaire was developed and administered to undergraduate students at an elite Northeastern university. Unlike the other two analyses, the results from this study are not generalizable; however, they should provide an indication of whether the trends identified with gender and racial attitudes may carry over to opinions regarding sexual minorities. Outcomes are attitudes towards legalizing gay marriage and providing same-sex couples with job benefits
The results confirm the link between feelings of threat and negative views of the out-group. All three analyses demonstrate that individual threat and group threat are simultaneously associated with opposition to policies aiding the subordinate group. Furthermore, the results suggest the possibility of a proxy relationship between individual threat and group threat.

title: Application of the Difference Map Algorithm to Protein Folding
abstract: This dissertation focuses on the application of a new search algorithm, the difference map, to the problem of protein structure prediction.
First a short review of protein structure is given to explain the terms and concepts used in the following chapters. A brief description of the current structure determination techniques (x-ray diffraction, NMR) are given, but the bulk of this dissertation is focused on ab initio structure prediction. Using ab initio methods, the native fold of a protein is assumed to be the global minimum of a high dimensional energy function. The current methods for minimizing this energy function are reviewed. The next chapter introduces a new search algorithm, the difference map. The difference map has been applied to many fields and problems where an exhaustive search is not feasible. A brief description of its historical development is given. Following this is an explanation of how the algorithm efficiently searches a high dimensional search space. A program called the difference map explorer was created to explore the effects of various difference map parameters on the search dynamics of the algorithm.
The application of the difference map to the problem of protein energy minimization is demonstrated in chapter 3. In this chapter, the rate at which the difference map produces low energy protein conformations is compared with that of a Monte Carlo based search algorithm, parallel tempering. It is shown that the difference map finds low energy protein conformations at a significantly higher rate than parallel tempering. The final chapter describes in detail NENA, the software implementation of the difference map folding algorithm.

title: Heat kernel estimates for inner uniform subsets of Harnack-type Dirichlet space
abstract: The main result of this thesis is the two-sided heat kernel estimates for both Dirichlet and Neumann problem in any inner uniform domain of the Euclidean space $\mathbb R^n$. The results of this thesis hold more generally for any inner uniform domain in many other spaces with Gaussian-type heat kernel estimates. We assume that the heat equation is associated with a local divergence form differential operator, or more generally with a strictly local Dirichlet form on a complete locally compact metric space. Other results include the (parabolic) Harnack inequality and the boundary Harnack principle.

title: Reindeer Nutrition and Pasture Analysis in the Mongolian Taiga
abstract: The research for this thesis has taken place over the last two years (2005-2006) in the northern-most pinnacle of Mongolia only miles from the Russian border. It is aimed at assessing nutritional availability, range quality and utilization by domesticated reindeer (Rangifer tarandus tarandus) in a small sliver of taiga ecosystem inhabited by a nomad reindeer-herding people called the Tsaatan. Indigenous reindeer herding practices and cultural strategies link the survivability of the people with the survivability of their reindeer. The period of Soviet occupation in Mongolia from 1921 to 1991 caused massive damage to the social fabric of Tsaatan culture and also herd health. Since 1991, the Tsaatan have been attempting to revive their culture in post-soviet, Mongolian democracy. Through dairy, packing, riding, meat and other by-products, reindeer provide the raw materials and power the Tsaatan need to survive in this cold mountainous region of Mongolia.
Though a multitude of health problems effect the herd today including inbreeding and zoonotic diseases such as Brucellosis, I believe the herd?s recovery is predicated on first establishing better herd nutrition. Herd demographic data collected by myself and other researchers in 2006 showed a correlation between herd body condition and management strategies/forage quality [Appendix 1]. With the underlying assumption that heard health is influenced by nutrition, this study set out to collect the first set of data on forage availability/quality in Tsaatan pastures. My hypothesis was that both availability and diet composition vary from other reindeer groups and warrant a dynamic set of considerations in terms of best-management policies for the herd.

title: Triggers and Ranked Keyword Searches over Virtual XML Views
abstract: Current systems that publish XML/relational data using XML views are passive in the sense that they can only respond to user-initiated queries over the XML views. Further, existing systems do not support ranked keyword searches over virtual XML views, which is important for exploring and retrieving information from large views. In this dissertation, we propose an XML view system whereby users can place active triggers on virtual (unmaterialized) XML views, and can efficiently evaluate keyword search queries over such views. In this architecture, we present scalable and efficient techniques for processing triggers over nested views by leveraging existing support for SQL triggers over flat relations in commercial relational databases. When evaluating the keyword search queries, our approach exploits indices present on the base data and thereby avoids computing large parts of the view that are not relevant to the query results. Another feature of the

algorithm is that it supports top-k results for queries over the virtual view, and the resulting rank order is the same as if the view was materialized. We have implemented our proposed techniques in the context of the Quark XML middleware system. Our performance results indicate that our proposed techniques are a feasible approach to supporting triggers and ranked keyword searches over virtual XML views.

title: Effects of Concentrate Addition on In Vitro Rumen Fluid pH and Forage Fiber Digestion
abstract: Further characterization rumen digestion could aid in development of a more efficient diet. The objective was to determine the early effects (0-6h) of concentrate type on rumen pH and forage digestion. Two forages, orchard grass and corn (Zea mays L.) stover, were combined in a 50:50 ratio with 5 concentrate treatments (no concentrate, corn meal, corn gluten meal, barley (Hordeum vulgare L.) and wheat (Triticum aestivum L.)). Samples were incubated in vitro in a 1:4 buffer to rumen fluid mixture for 420 min. The pH was measured at intervals throughout the trial and samples were collected for volatile fatty acid (VFA) analysis. Forage samples alone had significantly lower pH ($P<0.05$) than those samples containing concentrate. For corn stover samples, this correlates with a high mean lactic acid concentration (535 ppm). The final study measured change in pH and the difference in neutral detergent fiber (NDF) digestibility of four concentrate treatments (no concentrate, corn meal, corn gluten meal, and barley). Two sample distribution methods were tested; forage and concentrate were mixed together in the same filter bag or separated into individual bags. Barley had the largest inhibitory effect on fiber digestion and caused the largest decline in pH. Treatments with feeds in the same bag showed larger differences in pH and digestibility. Results suggest a diet containing a mixture of forages or, a mixture of corn and forage minimizes declines in rumen pH. They also suggest the study of associative effects is impeded by separation of feeds through filter bags.

title: Comparison of Antimicrobial Resistance Patterns Between Salmonella Enterica Subsp. Enterica and Escherichia Coli in Dairy Calves
abstract: The primary objective of this study was to compare antimicrobial resistance patterns of Salmonella enterica with Escherichia coli isolated from the same dairy calves. Fecal samples were collected from February 2004 to September 2005 from 74 calves. Calves with at least one Salmonella isolate and one E.coli isolate were included in our analysis. The 148 isolates collected from the 74 calves were tested using a broth tube dilution method for determining resistance to several antimicrobial agents (n=14): AMP, APR, CEF, CHL, ENR, FLO, GEN, NEO, OXY, SPE, SCH, SDI, STH, and TRI. Considering resistance to individual drugs, the percent of E.coli isolates with resistance was over 50 for 11 drugs and the percent of Salmonella isolates resistant was over 50 for 9 drugs. From the antimicrobial resistance patterns generated for E.coli (n=42) and Salmonella (n= 22), the bacteria were found to have 6 identical patterns in common. From these 6 patterns the most common pattern showed resistance to AMP, CEF, CHL, FLO, NEO, OXY, SCH, SDI, and STH. The association of antimicrobial resistance between Salmonella and E.coli for the same calves for individual antimicrobial agents proved not statistically significant. This study showed that resistance to drug classes important in human and animal medicine was common in Salmonella and E.coli from clinically ill calves. Overall, E.coli isolates were more resistant than Salmonella. While there were shared patterns of resistance (n=6) between Salmonella and E.coli, Salmonella isolates were not significantly more likely to be resistant to individual antibiotics if a calf had a resistant E.coli. Results suggest that selection pressure from recent

exposure to drugs or interspecific gene transfer was not resulting in a strong association of resistance between the bacteria.

title: Effect of Changes in Weaning Age on Carcass Traits in Forage Finished Beef Cattle
abstract: An increase in percent intramuscular fat (%IMF) and average daily gain (ADG) are advantageous to the profitability and consumer palatability of forage finished beef. The effects of weaning age in beef cattle fed an all forage diet on measure of weight gain and carcass quality were analyzed over two years of calf data. Measures of gain included average daily gain, weight per day of age (WDA), and weight at the conclusion of trial two weaning (CW2). Measures of carcass quality included percent intramuscular fat, Longissimus muscle area (REA), rib fat (BF), finished live-weight (FW), rump fat (RF) at the conclusion of trial two weaning, empty body fat (EBF) and Longissimus muscle area as a function of finished weight (REA/FW). Angus x Simmental beef calves (N=50 over two years) were weaned at two distinct ages. In both trials, calves were weaned using a calf-weaner, a plastic removable nose ring used for low stress weaning. In trial one calves were weaned at the time normally practiced, approximately 157 (+13) days of age in 2004 and 182.7 (+ 9.7) days of age in 2005. In trial two the time of weaning was delayed to 338.5 (+ 13.6) days of age in 2004 and 266.1 (+ 8.4) days of age in 2005. Following weaning in both trails, calves were fed an all forage diet. For calves born in 2004, carcass data for both weaning groups was gathered by ultrasound at 597(+ 13.6) days of age; in 2005, calves from both trails were analyzed by ultrasound at approximately 554(+ 8.9) days of age. The calves in which weaning was delayed showed numerically higher values for percent intramuscular fat, rib eye area, rump fat, back fat, finished weight, weight per day of age, empty body fat (percent), and rib eye area as a function of finished weight. These differences however were generally not statistically significant using the general linear model in SAS (1998), and analyzing least square means using The Waller-Duncan K-ratio t test. There was a statistically significant difference in WDA and CW2 for 2005 born calves. The results of this research potentially show a relationship between delaying weaning and an increase in the carcass quality of forage finished beef. As farmers producing forage finished beef seek to compete for market share in a market primarily dominated by grain finished, highly marbled, younger carcasses, a delay in weaning age may produce carcasses which are more highly competitive in the current market and capable of better suiting consumer preferences.

title: Maturity of the Lamb Immune System
abstract: Vaccines targeting specific threats to lamb health could be immensely instrumental in curbing high levels of lamb mortality in the U.S. lamb industry. However, the age at which vaccine administration would be most beneficial is currently unspecified due to limited knowledge of when lambs become immunocompetent. This study?s main objective was to determine the effect of age on the immunological competency of sheep in order to determine the optimal schedule for vaccinating lambs. An experiment was designed to examine the ability of lambs of varying ages to mount an antigen-specific immune response against Keyhole Limpet Hemocyanin (KLH) after vaccination with KLH in 10% aluminum hydroxide as the adjuvant. Groups of five lambs were vaccinated subcutaneously with one of three treatments (vaccine, control, adjuvant only) three times at two week intervals over a total of six weeks. The age at administration of the treatment was also variable (n=5); the lambs were either 0, 5, or 40 weeks of age at the start of their respective six week vaccine

trial. Three blood samples were taken immediately prior to the second and third treatment and two weeks after the third. Lymphocyte proliferation, and production of total immunoglobulin (Ig), and KLH-specific Ig were measured. An increase in lymphocyte production in vaccinated animals in response to vaccines was seen as early as 4 weeks of age, after two vaccines. The production of anti-KLH Ab in vaccinated lambs began after the first vaccination and had a fold response four times as high as control and adjuvant-only animals when sampled two weeks after the first vaccination.

title: Effects of Age, Dominance, and Mating System on Vocal Consistency in Mockingbirds (Aves: Mimidae)
abstract: While many studies have looked at selection for large repertoire sizes in birds, few have explored the potential for selection on the ability to sing each type in the repertoire consistently. I explored this issue by studying the consistency with which two closely related species of mockingbirds, i.e. the northern (Mimus polyglottos) and the tropical mockingbird (M. gilvus), repeated each syllable type. I hypothesized that if there is selection for singing ability and not just for an increase in repertoire size, it could be expected that syllable consistency should be (1) higher in older, more experienced individuals, (2) higher in species with higher potential for sexual selection via female choice (i.e. higher in the northern versus the tropical mockingbird) and (3) higher in males expected to be of higher quality (i.e. in dominant versus subordinate birds). I found that song consistency could be improved with practice because tropical mockingbirds became more consistent with age. When comparing across male types, I found that consistency was higher in northern and dominant tropical mockingbirds than in subordinate tropical mockingbirds (although the data suggests that dominant tropical mockingbirds that compete with subordinates for breeding may not be much better singers than these subordinates). I suggest that the lack of significant differences between northern mockingbirds and dominant tropical mockingbirds could be a product of a trade-off between repertoire size and singing consistency because as the number of types in a repertoire increases, the opportunities to practice each type are reduced.

title: Investigations into Colony Identity in a Social Spider: Does Delena cancerides Utilize Chemical Cues to Distinguish Between Kin and Non-kin?
abstract: The presence of recognition systems, though oft-studied and well documented in the eusocial insects, has been largely unreported among the spiders. Most spider species are solitary and cannibalistic, such that kin recognition is not particularly advantageous, and most social spiders do not apparently differentiate between relatives and non-relatives. However, Delena cancerides, a social huntsman spider from southern Australia, is the only social spider known to respond aggressively to introduced non-relatives and has been shown to preferentially consume non-kin in starvation experiments. It is hypothesized that chemical cues mediate the differentiation of related colony mates from non-colony mates, and that D. cancerides prefer exposure to cues derived from their natal colony to those derived from an alien colony. I used a three choice olfactometer to implement an olfactory preference assay with D. cancerides, using the degree of exploration in the olfactometer to divide trials into three analyzable groups. Movement within the olfactometer during trials was highly non-random. Spiders in the group characterized by exploration of both the same-colony and foreign-colony stimuli settled with their same-colony stimulus at the end of the trial significantly more than

predicted by chance. However, none of the three trial groups spent significantly more time in the presence of a same-colony stimulus than predicted by random motion. Spiders spent significantly more time in the presence of conspecific stimuli, from either same- or foreign-colonies, than predicted by random motion in two of three trial groups, suggesting that recognition of conspecifics and the tendency to aggregate is also mediated chemically.

title: Taxonomic Revision of the Genus Schildia Aldrich, 1923 (Diptera: Asilidae: Leptogastrinae) with Descriptions of New Extant and Fossil Species
abstract: Schildia Aldrich, 1923, a distinctive and rare genus of Leptogastrinae (Diptera: Asilidae), is revised. Twelve species are recognized, of which five are new to science. The nine extant species are Neotropical, Afrotropical, and Oriental in distribution. The extant Neotropical species are S. alphus Martin, 1975; S. caliginosa sp. n., described from southern Venezuela; S. fragilis (Carerra, 1944); S. guatemalae Martin, 1975; S. gracillima (Walker, 1855); S. jamaicensis Farr, 1963; S. microthorax Aldrich, 1923; and S. zonae Martin, 1975. S. ocellata Martin, 1975 is synonymized with S. gracillima. The extant Afrotropical species is S. adina sp. n., described from extant and copal (0-11000 years ago) specimens from Madagascar. The extant Oriental species is S. malaya sp. n., described from Kedah, Malaysia. Two extinct species, S. angustifrons and S. martini, are newly described from Dominican amber (15-20 million years ago). Redescriptions and descriptions of the genus and all extant and fossil species are provided. An identification key to the extant and fossil species is presented. Illustrations, photographs, and scanning electron micrographs are provided to support the descriptions and key. Distribution, biogeography, occurrence in biodiversity hotspots, seasonal incidence, and biology are discussed. The geographic distributions of several species are expanded. Potential reasons are explored to explain why Schildia, previously thought to be strictly Neotropical, is also found in Madagascar and Malaysia. Tentative minimum age of the genus is discussed in light of new fossil and biogeographical data.

title: A Multi-faceted Analysis of Spinosad Resistance in the House Fly (Musca domestica L.)
abstract: House flies are important vectors of a number of animal and human pathogens, thus controlling them is of great importance. Commercial insecticide control of house flies is limited to a few chemicals, and the development of resistance to these chemicals is an ongoing concern. Therefore, finding new effective insecticides is critical. Spinosad is a relatively new promising insecticide that was released in 2005 for house fly control. It is derived from the bacterium Saccharopolyspora spinosa. It is highly effective against pest species and is thought to have a unique mode of action. A resistant laboratory house fly strain was developed and studies indicate the resistance mechanism is unique, recessive, and located on autosome 1. Although house fly resistance to spinosad has been developed in the laboratory, resistance in field populations has not been characterized. In this study I monitored spinosad resistance at several dairy, hog and poultry farms over the summers of 2004 and 2005. Results showed that there was a variation in baseline susceptibility between different field sites, but no development of resistance was observed. Due to limitations of insecticide bioassays, developing a more sensitive resistance detection method and identifying the gene responsible for resistance will be important for future monitoring programs. As part of an important step in determining the gene for resistance, I linked a number of nicotinic acetylcholine receptor (nAChR) subunits to a particular house

fly autosome. Spinosad toxicity is due to interactions with nAChRs and is associated with autosome 1. Of the four genes analyzed, two (Md?5 and Md?6) were associated with autosome 1, one (Md?2) was associated with autosome 2, and one gene association (Md?3) was not determined. Lastly, I assessed the fitness effects of spinosad resistance on mating competition. I found that a laboratory susceptible strain had a mating advantage over a laboratory spinosad resistant strain.

title: A Survey of the Dung Beetles in Cattle Manure on Pastures of an Organic and a Conventional Dairy Farm in New York State
abstract: Dairy is an important part of New York state agriculture. Many dung beetle species live in pasture cattle manure. This study was a survey of the species of beetles (Scarabaeidae, Geotrupidae, Hydrophilidae, and Histeridae) in dairy cattle manure from pastures of two different farms, one conventional and one organic. Aphodius species, specifically A. granarius, A. haemorrhoidalis, and A. stercorus were the most numerous beetles (approximately 21% of the identified beetles), excluding the small, unidentified Hydrophilidae less than 2 mm in length. This contrasts with results of similar studies using the same protocol in North Carolina where Onthophagus taurus was the most abundant species of dung beetle on pastures, suggesting that latitude has a an effect on the composition of dung beetle communities.

title: Shooting Blanks: Mate Choice and Determination in a Parasitically Castrated Snail, Littorina littorea
abstract: The trematode parasite Cryptocotyle lingua completely castrates both male and female Littorina littorea snails that it infects. Selection should favor males who distinguish between fertile and parasitically-castrated females when choosing mates. I addressed this question by sampling mating pairs in the intertidal and those snails in their immediate vicinity. I compared the frequency of infection in females in mating pairs with that of ambient non-mating females to determine if the frequency of infection was significantly lower in mating females. In addition, to test the assumption that infected males were physiologically incapable of initiating copulatory behavior, I compared the infection prevalence of mating males with that of non-mating ambient males. I found that there was no significant difference in the infection prevalence between mating and non-mating females, indicating that males were not distinguishing between infected and uninfected females. This may be the case due to high levels of gene flow between highly infected and unexposed populations, insignificant costs associated with wasted mating attempts for males, or low heritability of the means for detecting infection in females. Infection prevalence in mating males was nearly significantly lower than that of non-mating males. However, the surprising frequency of infected males mating (15%) suggests that gonad health is not a pre-requisite for initiating copulatory behavior.

title: Assessing the Costs of Group Living: Comparing Metabolic Physiology and Growth in Social and Solitary Spiders
abstract: Sociality in arachnids is extremely rare though well documented for the few cases that exist. However,

no research to date has examined the metabolic and growth characteristics associated with social behavior. Delena cancerides is a social huntsman spider that closely overlaps in distribution with several closely related species of solitary huntsmen, providing a unique opportunity for comparison. I compared the metabolic rate of D. cancerides to other species of solitary huntsman using a closed-system respirometer. I also compared the growth, survival and molting frequency of D. cancerides spiderlings in solo and group treatments to those of solitary huntsman species. Delena cancerides had a significantly lower mass-specific metabolic rate than all other species to which it was compared. This is explained in the context of reduced food availability per individual for prolonged periods of time due to sharing. Delena cancerides spiderlings did not differ from other species when housed alone, but grew significantly more in group environments than did solitary species. Mortality was lowest for D. cancerides living in groups than for any other species living in groups. There was no difference for any species in molting patterns between solo and group treatments. D. cancerides molted consistently earlier and more often than the species to which it was compared. The consequences of these findings are discussed in the context of prey-sharing and avoidance of cannibalism.

title: Advocacy and Interventions: Readings in Communication and Development
abstract: As the 21st century rolled out, communication in relation to development became more prominent in the international community. Efforts to reach the Millennium Development Goals sharpened our attention on communication with many asking how the new information and communication technologies could accelerate progress toward the Goals. This book addresses these issues. It is intended to be a "practical" book. It is filled with examples and case studies that illustrate ways that carefully planned and implemented communication interventions have produced positive results. It shows how approaches such as social marketing, extension, participation, and entertainment have contributed to development initiatives. Many of these have used media and the new information and communication technologies. "Advocacy and Interventions" includes ideas from people who have experienced the challenges of communicating effectively in development programs. The book is also based on the author's own insights from almost four decades of communication and development experience in countries ranging from Guatemala to Western Samoa, with many other stops in Asia, Africa and Latin America. "Advocacy and Interventions" is especially suitable for policy makers, project planners and advanced courses in development communication or rural development.

title: Systematic Effects of Local Large Scale Structure on the Measured Expansion History of the Universe
abstract: Committee members: Ira Wasserman, Eanna Flanagan, Jim AlexanderWe discuss some of the ways that local cosmological inhomogeneity has been found to affect our interpretation of the measurements of the redshifts and luminosity distances of Type Ia supernovae, so that we may ask: Can a matter dominated universe, with gravity governed by general relativity, appear to be accelerating? This discussion focuses on the systematic corrections to measured cosmological parameters that one would find as a result of the ``fitting problem", wherein the fitting of data to what we would see in a homogeneous universe introduces errors due to the nonlinearity of general relativity. It has been suggested that this fitting effect could explain the supernova data without introducing dark energy or modifications of general relativity. We explore this claim within the context of several cosmological scenarios, all of which use standard general relativity and are dust dominated, with no dark energy. First, we use the spherically-symmetric Lema\^{i}tre-Tolman-Bondi cosmological

models, then we look at a simple model for cosmological voids and sheets, and finally we treat the problem in full three dimensional generality. In each of these contexts, we analyze the systematic corrections to the luminosity distances and redshifts of Type Ia supernovae that result from local large scale structure. We then find how such corrections affect the properties of the Universe that we infer from this measured luminosity distance-redshift relation. We show how, in principle, a very large degree of inhomogeneity can trick us into thinking that the expansion of the Universe is accelerating when it is not. However, within the confines of more realistic models, such effects are shown to be small. In the full three dimensional case, we find that the error in the best-fit cosmological constant is approximately $\Delta\Omega_{\Lambda}\approx 0.004$ for a large sample of supernovae at small redshifts, between $z_{min}=0.02$ and $z_{max}=0.15$. Although this error is not large enough to explain the measured cosmological constant value $\Omega_{\Lambda}\approx 0.7$, it is still a potentially significant systematic error that has not been accounted for previously.The National Science Foundation, NASA, Cornell University, the American Association of University Women

title: Use of a Combinatorial Search for the Discovery of New Fuel Cell Electrocatalysts
abstract: Francis J. DiSalvo, R. Bruce van Dover, Hector AbrunaPolymer electrolyte fuel cells are devices that convert chemical energy to electrical energy through oxidation of a fuel (typically hydrogen, methanol, or ethanol) at the anode and reduction of oxygen at the cathode. They have the potential to be more efficient and less environmentally harmful than combustion engines and other heat transfer processes for the extraction of energy. Pt is a typical anode electrocatalyst, but it suffers from slow kinetics for methanol and ethanol oxidation and is susceptible to poisoning from impurities, even for hydrogen oxidation. Although several notable materials discoveries have improved anode electrocatalysts, the materials are far from ideal. While previous research has shown that ordered intermetallic compounds may be better electrocatalysts than those presently used, an investigation through all possible binary and ternary component electrocatalysts using traditional synthesis methods would take an inordinate amount of time.
We use a combinatorial method to more quickly search through the majority of compositions in binary and ternary phase diagrams for better fuel cell anode electrocatalysts than Pt. We deposit thin film composition spreads of up to three elements that cover up to 75% of a phase diagram. We test the compositions for electrocatalytic activity for methanol and ethanol oxidation using a fluorescence screening method and characterize the composition, surface morphology, and crystal structure of active regions.
We synthesized and tested films of Pt-Ru-X (where X = Pb, Co, Ni, Ag, V, Mo, Fe, In, and Sb), Pt-Pb-X (where X = Bi, Sn, Mo, Co, Cr, Fe, Nb, Ni, Si, Ta, and In), and Pt-Nb-X (where X = Co, In, Ni, Sb, and Fe). Of all the films tested, a Pt-Pb-Ta film deposited at 405C has an active region for methanol oxidation with the lowest onset potential of -50 +/- 25 mV vs. Ag/AgCl, bulk composition of Pt0.65Pb0.02Ta0.24O0.09 (measured by WDS), and an fcc Pt structure type. Pt-Ru-Pb films deposited at ambient temperature have regions with the lowest onset potentials for ethanol oxidation: the average onset potential is -235 +/- 25 mV vs. Ag/AgCl, the average bulk composition is Pt0.42Ru0.45Pb0.04O0.09 (measured by WDS), and the structure type is fcc Pt.Department of Energy, National Science Foundation

title: Distribution of Cs-137 in stream sediments and stream banks in the upper Susquehanna basin - 2006
abstract: This project is part of the Cornell University Agricultural Ecosystems Program: Understanding Sources and Sinks of Nutrients and Sediment in the Upper Susquehanna River Basin. Principal Investigators: Robert Howarth, Cornell University, Department of Ecology and Evolutionary Biology, Professor; Johannes Lehmann, Cornell University, Department of Crop and Soil Sciences, Associate Professor; Alice Pell, Cornell University, Department of Animal Sciences, Professor; Roxanne Marino, Cornell University, Department of Ecology and Evolutionary Biology, Senior Research Associate.This study expanded on our previous regional study of sediment sources in central New York by using 137Cs and other tracers to quantify the relative importance of sediment producing processes in the upper Susquehanna watershed. We sampled recently eroded sediments in a suite of watersheds in the upper Susquehanna basin of NY with contrasting historical and current land uses, and differing geomorphic and stream channel characteristics, focusing on likely high sediment-producing areas to identify subbasins with high levels of sediment contributed by bank erosion. By fingerprinting stream sediment sources, we hope to improve the basis for conceptualizing the process of erosion and sediment delivery and for devising and implementing effective sediment control programs. The most effective work with sediment tracers has involved the analysis of nuclear bomb-derived and natural fallout radionuclides that bond to sediment. Fallout radionuclides generally are retained in the upper few cm of soil; hence, they can be employed to analyze whether stream sediments have been eroded recently from surface sources or represent erosion from deeper sources like rills, gullies and streambanks. See the following for related work using similar methods: Nagle,G.N., T.J. Fahey, J.C. Ritchie, and P.B. Woodbury. 2007. title: Woman's Identity and the Qur'an: A New Reading

abstract: Copyright 2004, University Press of Florida.
For the Cornell Community: http://racereligion.library.cornell.edu/religion/ebook_profile028.php.
A Paperback edition (2006): http://www.upf.com/book.asp?id=BARAZF04.
See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#1An original and uncompromising study of the Qur'anic foundations of women's identity and agency, this book is a bold call to Muslim women and men to reread and reinterpret the Qur'an, Islam's most authoritative source, and to discover within its revelations an inherent affirmation of gender equality.
Nimat Hafez Barazangi asserts that Muslim women have been generally excluded from equal agency, from full participation in Islamic society, and thus from full and equal Islamic identity, primarily because of patriarchal readings of the Qur'an and the entire range of early Qur'anic literature. Based on her pedagogical study of the sacred text, she argues that Islamic higher learning is a basic human right, that women have equal authority to participate in the interpretation of Islamic primary sources, and that women will realize their just role in society and their potential as human beings only when they are involved in the interpretation of the Qur'an. Consequently, a Muslim woman's relationship with God must not be dependent on her husband's or father's moral agency.
Barazangi, an American Muslim of Syrian origin, is a scholar, an activist, and a concerned feminist. Her analysis of the complex interaction of gender, religion, and the power of knowledge for self-identity offers a paradigm shift in Islamic studies. She documents the historical development of Islamic thought and describes how Muslim males have arrived at the prevailing exclusionary positions. She considers the issues of dependent morality and of modesty, especially in attire--a polarizing subject for many Muslim women. She integrates her analysis with interviews she conducted with Muslim women in the United States and Canada, comparing that data with information from a parallel group in Syria and with historical cases. She concludes that the majority of Muslim women today are not educated even for a complementary role in society.
The book offers a curricular framework for self-learning that could prepare Muslim women for an active role in citizenship and policy making in a pluralistic society and may serve as a guideline for moving toward a "gender revolution." Her main thesis, if carried out in the lives of Muslims in America or elsewhere, would be so radical and liberating that her discourse is more powerful than those of many Muslim feminists. She writes, "I intend this book to affirm the self-identity of the Muslim woman as an autonomous spiritual and intellectual human being."

The definitive publisher-authenticated version is available through Oxford University Press: http://www.oup.com/us/catalog/general/subject/ReligionTheology/

Islam/?ci=0195148037&view=usa.
See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#1The dynamic relationship between political, social and educational changes is central to determining whether educational reform occurred in the Muslim world during the nineteenth and twentieth centuries. Changes in curricular and instructional policies and their implications for intellectual and cultural development are discussed in relation to four major issues.
The Muslim world initially rejected as irrelevant changes introduced from Europe in the early nineteenth century. Changes in technical, military, and vocational training dictated by local rulers and elites did not conform to the traditional educational practices that were the remnants of Islamic education. Comparing these practices with recent changes runs the risk of overstating where and how educational reform has taken place.
Available literature indicates that old practices were not reformed and changes resulted in no significant attitudinal or cultural development. Setting the European utilitarian and the Muslim altruistic modes against each other resulted in centralized state-controlled educational institutions and a complete departure from Islamic education.
The intellectual stagnation that characterized the Muslim world since the early fourteenth century remained despite mass and compulsory schooling in the postcolonial era. Recent reports indicate school and teacher shortages, low educational quality, lack of planning and of curricular and instructional compatibility, and disparity in access to and completion of all types and levels of education between the sexes and between rich and poor and rural and urban populations.

title: Religious Education
abstract: Copyright 1995, Oxford University Press. This is a pre-copyedited version of an article accepted for publication in the edited Oxford Encyclopedia of the Modern Islamic World following peer review. The definitive publisher-authenticated version is available through Oxford University Press: http://www.oup.com/us/catalog/general/subject/ReligionTheology/Islam/?ci=0195148037&view=usa. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#1Internal political and social movements of the eighteenth, nineteenth, and twentieth centuries neglected Islamic education within the Muslim world and allowed external secular and missionary ideas to turn it into "religious" education. Variations in worldview and interpretation of Qur'anic principles of education resulted in emphasis on form over essence in educating Muslims.
Historical accounts of Islamic/Muslim education provide a variety of perspectives on its nature and the function of its traditional institutions. Cultural and political restraints ended Islamic education as a functional system aimed at understanding and appropriating Qur?anic pedagogical principles and limited it to "religious" knowledge confined to selected males. Islamic education has recently been confused with a subject matter, "religion," or a moral, social codes, akhlaq. The primacy of formalized and juridical education over the informal development of Islamic character resulted in curricular and instructional differentiation between class and gender, a separation of "Islamic" and "non-Islamic" knowledge, and a dichotomy between ideal and practice in Muslim education.

title: Understanding Muslim Women's Self-Identity and Resistance to Feminism and Participatory Action

Research
abstract: Copyright 2004, Praeger Publishing.
This is a pre-copyedited version of an article accepted for publication in the edited book Traveling Companions: Feminism, Teaching, and Action Research, following peer review. The definitive publisher-authenticated version is available through Praeger Publishing: http://www.greenwood.com/catalog/C8027.aspx. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2While headed in similar directions, rarely have feminist researchers and participatory action researchers acknowledged each other as collaborators with mutually important contributions to the journey. Through the work presented in this volume, the contributors hope to influence feminist scholarship to be more participatory and action-oriented, and participatory action research to be more grounded in feminist theories and values.
This book has two distinct yet interrelated and intertwining aims. First, it creates a space for a diverse group of educators, researchers, and scholars to grapple with the multiple and complex issues that are threaded throughout feminist and action research. Second, it seeks to examine how action research and feminist research can complement each other in developing strategies for engaging in collaborative research that is rooted in activism and productive change.

title: Muslim Women's Education: Between East and West
abstract: Copyright 2004, Nimat Hafez Barazangi.
This is a pre-published version of an article accepted for publication in the edited book Women in Islamic and Judaic Societies following peer review to be published by Holmes and Meier: http://www.holmesandmeier.com. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2The media and the popular culture literature in America and Europe are not the only biased groups in portraying women in Islam as "oppressed" and that their liberation can take place only outside Islam. Contrary to my trust in the impartiality of Western scholarly and activists groups, I am finding that such groups are as inequitable when it comes to addressing the "Muslim woman question" from within the framework of Islam. Empirical and historical findings in my current research on Muslim women's education in western societies, such as in North America, suggest that the absence of concerns for Muslim women's religious education is not only evident, but particularly polarized during the last two decades of the twentieth centuries. Though many of these groups are advocates of Judo-Christian women's participation in their respective religious theological and scholarly ranks, none of these groups raises the issue of Muslim women inclusion in decision-making and scholarly ranks among Muslim communities.
The Qur'an and the Hadith are rich in precepts that speak of Almighty God's design for harmonious social order and humanity's responsibility for understanding God's design and working from within it. For many Muslims, including those active in North America, citing these precepts is enough to prove that Islam has always embraced a well integrated educational imperative and comprehensive knowledge of the Islamic teachings for all Muslims. Few, however, are critical when the discussion concerns women's Islamic education and the women's role as preservers of culture and as the primary educators within the faith of Islam. These few Muslims may readily acknowledge that women have more power in Islam than most Westerners realize, but when the question of allowing more women to become Islamic scholars and jurists is raised, the issue becomes that of women's primary role as nurturing mother and wife instead of educating scholar and a partner in the interpretation of the tradition.
Meanwhile, Muslim women in the USA and Canada, as generally is the case in other Western societies, are not free to practice certain aspects of Islam with the excuse that women are being oppressed by Islam. While Muslim women are trying to build their own agenda for emancipation, they are being torn between secular

humanists who do not allow them to practice their own reading of the religion, and the Muslims who still think that a women's Islamicity is expressed through the wearing of a headcover and seclusion and by her male household.
Analyzing this polarization in the context of Muslim women's education historically, since the interaction between the West and Muslim societies has intensified in late nineteenth century, and empirically, using North American Muslim women as the case-in-point, indicates a discrepancy in the world views on education, on Islamic education, and on women's education. This discrepancy resulted in a tension between Muslims and Westerners in which Muslim women's education suffered the brunt. By synthesizing these discrepancies and the resulting historical and contemporary practices, I will conclude with some suggestions for developing an integrated educational strategies for Muslim women within the Islamic framework and in the contemporary Western social context.

title: Domestic Democracy: The Road to National and International Democracy
abstract: Copyright 2003, Nimat Hafez Barazangi. See also: http://www.islam-democracy.org/4th_Annual_Conference-Barazangi_paper.asp; http://www.eself-learning-arabic.cornell.edu/publications.htm#2In this paper, I draw an analogy between participatory democracy in the Qur`anic gender revolution and the national-international democratic relationship. Qur`anic relations create an active process of individual political consciousness and social action, while the present national-international relations hardly create national awareness or global justice. I argue that antithetical to the active process of the Qur`anic gender revolution stands the analysis of Muslim women's role in the political discourse and the governance of Muslim societies merely within gender "add-on" strategies, particularly as discussed in contemporary Western academic and Muslim traditionalist discourses.
As a Muslim woman scholar-activist, I view the use of gender and other constructs as deactivating factors in the conscious process of participatory democracy within Islam. This deactivation of consciousness could explain why some Muslim women scholar-activists resist feminism that emphasizes universal group solidarity, without paying attention to individual worldviews. It could also explain why these women resist the predominantly Muslim male elite conception and practice of the consultative process (shura): participation is limited to the selected few, and women's participation is an "add-on" or only to address domestic issues.
By defining Islam as an action-oriented worldview that encompasses social, cultural, and political elements, including religious and secular "Ijtihad", I emphasize this worldview's reliance on human capacity to reason, and its goal being the construction of fair decision-making process that brings equilibrium (Taqwa). I bring to the surface underlying assumptions about how tension in the domestic relationship is reflected in tensions between national and international relationships. I specifically address the tension between feminists-generated conceptions of democracy vis-a-vis Muslim women's participatory democracy. These tensions are manifested on four levels: ontological or value claims, epistemological or knowledge claims, cultural or historical claims, and praxis or socialization claims. My focus will be on the relation between the power of knowledge and social and political constructs.
My goal is to develop a self-learning process to improve my own capacities and those of other Muslim women (and men) to control our destinies more effectively: to change life situations in the home, in the learning/work environment, and in the larger social context to support self-realization and self-determination. It means the ability to bridge individual political consciousness and social action to effect a cognitive and attitudinal change on the individual, social and political levels, mitigating potential resistance by both modernists and traditionalists.

title: Muslim Women's Islamic Higher Learning as a Human Right: Theory and PracticeArabic translation under the title: Da`una Natakalam: Mufakirat Amerikiyat Yaftahn Nawafidh Al-Iman (Dar Al-Fikr, 2002)
abstract: Copyright 2000, Syracuse University Press.
This is a pre-copyedited version of an article accepted for publication in the edited book Windows of Faith:Muslim Women Scholar-Activists in North America following peer review. The definitive publisher-authenticated version is available through Syracuse University Press: http://www.syracuseuniversitypress.syr.edu/books-in-print-series/women-religion.html. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2Limited access to Islamic higher learning is argued to be the basis for the Muslim woman's inability to emancipate and to self-identity as a Khalifa (trustee)--a Qur'anic mandate (or potential) of human existence. Muslim woman's reliance solely on others' interpretations to guide her spiritual and intellectual needs, be it those of Muslim or of non-Muslim men and women, is by itself an evidence that Muslim woman's right to understand, to consciously choose, and to actively act on her choice of Islam is being compromised. Full access to the Diin, the Islamic belief system, calls for the Muslim woman to take part in the interpretation of Islamic teachings of the Qur'an and the Hadith and to maintain the pedagogical dynamics of Islam, rather than being limited to maintaining the human re-production, the Muslim family structure, or the individual human rights as suggested by others.
My understanding of woman's gender justice vis-a-vis "liberation" within the Islamic worldview is based on epistemological reading (the philosophy of knowledge) of the Qur'an. The rationale behind the demand for woman's access to knowledge is derived from the Islamic framework. The methodologies of the discipline of education and learning and the struggle for human dignity that define the parameters for Muslim woman's emancipation are grounded in that framework. To examine her role as a human entity in the Qur'an does not merely concern the Muslim woman's "freedom of expression;" it concerns the woman as an autonomous spiritual and intellectual human being who can effect a change in history. The intent of this chapter and of my overall research is to make a contribution towards an educational and pedagogical interpretation of the Qur'an for women living in the post-modern era and thereby to produce an action plan for the Muslim woman to regain her identification with Islam. My analysis of empirical data concerning Muslim women's perception of Islam, the contemporary North American Muslim woman, in a historical context serves to clarify the meaning and the implications of Islamic higher learning regardless of these women's educational level. Preliminary observations suggest that the majority of Muslim women's movements do not aim to eliminate the tension between the two sexes by claiming sameness in the struggle for equality. Rather, their goal is Taqwa (to balance) the tensionback in favor of woman, as the Qur'an intends in the first place when human beings, male and female, were entrusted with individual rights and responsibilities toward themselves, each other, and the universe. I will argue that one of the basic principles of Islamic justice is gender justice.

The interpretations of these "equal" rights and responsibilities, however, stem from different perspectives of Islam. Muslim women groups are scattered on a continuum from the idealized polemic Muslim to the idealized static Western perspectives. Few are those who are making efforts to exact the balance between these perspectives.
The pedagogical implications of this research lies in : (1) intervening among Muslim men by coaching them to rethink and to act within the balanced perspective of Islam and its first source, the Qur'an, away from both the many layers of Muslim "taqlid " (following precedence) and from Western interpretations of Islam, (2) facilitating for Muslim women the environment and the means to realize their identity as autonomous spiritual and intellectual beings, and to realize the vastness of their task in educating themselves and others in Islam--encluding changing the entrenched paradigm of understanding Islam studies and its practice, and (3) integrating human-rights activists' concerns within the Qur'anic concerns for a just human society, where justice means the balance and fair play in the ideals and realities among all humans.

title: Self-identity as a Form of Democratization: The Syrian ExperienceTa`rif al Dhat Kashakl min Ashkal al Dimoqratiyah

This is a pre-copyedited version of an article accepted for publication in the edited book Democratization and Women's Grassroots Movements following peer review. The definitive publisher-authenticated version is available through the Indiana University Press: http://www.iupress.indiana.edu/catalog/product_info.php?cPath=1037_1100_1188&products_id=21083. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2This chapter combines historical research and a field reporting of participatory action research (PAR) with one of the grassroots women's movement in Syria. I will analyze the participatory or democratization efforts by members of this informally organized group (the group) that is working toward Muslim women's self-identity. Islamic higher learning and its relation to Islamic principles of gender justice provide the framework of this analysis.
Various factors have been affecting the priorities in women's Islamic knowledge and self-realization within the predominantly Muslim society of Syria. Even when the group emphasizes community-based informal education and social welfare activities, inside and outside views of Islam and Muslim women do influence the decision-making process. These decisions may concern matters ranging from the group agenda to the members' identifications with Islam. Interpreting Islam in this group's course of action is, consciously or unconsciously, affected by the domestic, national and international affairs of Syria. The present Syrian constitution does not declare Islam as a state religion. Yet, it is hardly possible to find a discussion of any issue in Syria or any other Middle Eastern and Muslim countries without invoking a "monolithic" representation of Islamic religion-cultural and political image. Meanwhile, no studies attempted to present the Islamic conceptual and pedagogical foundations for individuals' self- identity with Islam and the consequent civic decision-making process that affects the individual and communal life.
As a PAR researcher and educator, my working and reporting on this group is to argue for the change in discourse to be able to understand Muslim women's movement towards democratization. Some members of the group felt a need to further their indigenous educational strategies and invited me to participate in the group's study-circles. The group strategies consisted on reading the Qur'an and acting on what they learn. I knew of the group earlier and had informally observed some of their activities during subsequent visits to Syria. My presence in Syria for a period of three months annually during 1995-1997 helped develop this research and educational working relationship with the group.
Considering the Islamic principle of self-discipline for self-realization as neither inferior nor superior, this

group affirms autonomous responsibility as central to the Islamic religio-political process of educating. The group interpreted this principle to mean first-hand knowledge of Islam from its primary sources. Intimate knowledge of these sources (the Qur'an and the books of Hadith that contain the Prophet Muhammad's extrapolation of Qur'anic principles) is viewed as the only means to 'liberation.' Liberation is intended to rid oneself of the dichotomous agendas of "liberal" vis-a-vis "traditional" interpretations of Islam.3 The group's primary concern have been to understand and apply the Qur'anic way of life. Participatory decision-making process in the group, has been confined within the males' 'traditional' (i.e., grounded in absolute principles) interpretation of Islamic texts concerning the role of individual within a religio-socio-political structure of family and society. My work with this group, as a facilitator, takes the Islamic principle of self-discipline one step further to affirm self-identity within the Islamic premise of gender justice.
To facilitate their movement from the predominantly males' interpretations of the Islamic primary sources is to make the Islamic principle of trusteeship (Qur'an, 2:30) explicit through higher Islamic learning. A Muslim individual may not fulfill the Islamic pedagogy of a trustee without being able to autonomously choose, understand, and act on her choice of Islam as a worldview. This process requires both autonomous morality and intimate knowledge of the Qur'an before an individual can act as a trustee. Proxy or heternomous moralities--though represent prevalent practices--do not replace autonomous morality. Community welfare is central to Islamic principles of governing, but it does not preclude the primacy of autonomous morality as a form of self-governing. Within the guidance of the Qur'an and Hadith, when in conflict, the community collective welfare takes precedent over individual rights. My analysis of this group self-learning and self-governing is intended to present a form of democratization by this Syrian feminine movement to affirm Muslim women's agency. The group may not call its work democratic, nor feminine. This movement, though, has achieved and maintained some form of effective intellectual and civic participation despite the historical and cultural constraints that dominated the Syrian society, like other Muslim-Arab societies. My intention is not to compare this Syrian grassroots movement with other movements inside or outside Syria, but to change the perception of Muslim women's invisibility as an indicator of full dependency and/or oppression. By changing the discourse we find that "mainstream" literature concerning democratization, Syrian society, and Syrian Muslim Arab women have overlooked this type of groups because these groups are not connected to the center of power. Applying self-identity for self-realization approach within the Islamic framework of gender justice as a base of participation or democratization presents different set of assumptions. Self identity for self-realization approach presupposes higher Islamic learning to re-gain the power of knowledge as a means of active agency. Further synthesis of the context of this study, the history and culture of Syria provide evidence for this group's active agency.

title: Parents and Youth: Perceiving and Practicing Islam in North America

This is a reprint of a pre-copyedited version of an article accepted for publication in the edited book Muslim Families in North America following peer review. The definitive publisher-authenticated version is available through Alberta University Press: http://www.uap.ualberta.ca/UAP.asp?lid=41&bookid=162. This article was reprinted with permission by Temple University Press: http://www.temple.edu/tempress/titles/1255_reg.html
See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2This chapter examines how some Arab Muslim youth and families in North America perceive themselves both as Arabs and as Muslims in the context of Canadian and United States societies. Parents are concerned with how best to transmit the Islamic ideological and Arab cultural heritage to their children. One of their problems derives from differences

among Arab Muslims, who come from varied national origins and hold several interpretations of the Islamic view, not all of which are based on the Qur'an; as a result they also have different nationalistic attachments to their understanding of Arab heritage. A second problem arises between immigrant parents and their American-reared children. The children may participate in American culture to a greater extent than their parents, and they are constantly faced with the conceptual need to accommodate potentially conflicting points of view. Effective identity transmission requires the determination of the nature and extent of the different interpretations held by parents and their children and of the way these interpretations are reflected in their practice of Islam and association with the Arabic heritage.

title: The Equilibrium of Islamic Education: Has Muslim Women's Education Preserved the Religion?
abstract: Copyright 1998, Nimat Hafez Barazangi.
This is a pre-copyedited version of an article accepted for publication in the edited journal Religion and Education following peer review. The definitive publisher-authenticated version is available through Religion and Education: http://fp.uni.edu/jrae/islamicissuetoc.htm. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2I focus on issues of equilibrium in Muslim women's education to understand the tension between the ideals and practice and its ramifications for Islamic and Muslims' education in the United States. I argue that one maintainer of Muslim women's low effectiveness, perpetuated across new generations of Muslims, is the general perception that women are the preservers of culture and religion by proxy. The issue before us: How is it possible for a morally dependent individual to instill the character of autonomous spiritual and intellectual Muslim who can integrate effectively in a "pluralistic" society?
In addition to the various degrees of perceptions and misconceptions about Islam, religious tolerance and Multiculturalism, the problem is mainly of perceiving women, particularly Muslim women as morally dependent and, hence, socially and politically irrelevant or non-central to issues of Islamic education. With the exception of few, the majority of Muslim women are neither involved in the educational decsion-making of the Muslim community nor of this nation. Often perceived as preservers of customary practices instead of agents of cultural change and contributors to inter-cultural understanding, Muslim women and their Islamic higher learning has been marginalized.

title: Muslim Women's Islamic Higher Learning as a Human Right: The Action Plan
abstract: Copyright 1997, Syracuse University Press.
This is a pre-copyedited version of an article accepted for publication in the edited book Muslim Women and the Politics of Participation: Beijing Platform following peer review. The definitive publisher-authenticated version is available through the Syracuse University Press: http://syracuseuniversitypress.syr.edu/index.html. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2How do we expect the Muslim woman, collectively and individually, to identify with Islam as revered teachings and to act within its parameters, and to accommodate new human knowledge, be it that of a local Mufti's (clergy) injunction or a human rights advocate's recommendation, while neither Muslim societies nor human rights advocates recognize her self-identity as an autonomous spiritual and intellectual being? Accessing Islamic higher learning (deeper knowledge of the Islamic primary sources, the Quran and the authentic Hadith [prophetic tradition]), is argued to be the means by which the Muslim woman self-identity is recognized as a trustee.

Relying solely on others' interpretations to guide her spiritual and intellectual needs is by itself an evidence that the Muslim woman's right to understand, to consciously choose, and to actively act on her choice of Islam is being compromised. Muslim Woman's deeper knowledge of the Islamic primary sources is significant to defining her relationship to God and to others.
Muslim woman's understanding of "human rights" within the Islamic worldview, based on pedagogical reading (the art of learning and teaching) of the Quran is significant. I derive the rationale behind the demand for woman's educational rights from the Islamic worldview. The methodologies of the discipline of education and the strategies to implement the platform for action--that define the parameters for the Muslim woman's human rights--are grounded in that worldview. Examining her role as a human entity in the Quran does not merely concern the Muslim woman's "free choice;" it concerns her ability to maintain the pedagogical dynamics of Islam to effect a sustainable change in history. Self-realization of Muslim woman can only effect a sustainable change in history when that self-realization unfolds the meaning of trusteeship. The Quranic intention of trusteeship or vicegerency (AL-khilafah) (2:30) eliminates the replacement of the individual trusteeship by proxy.
The intent of this essay is to make a pedagogical interpretation of the word and the script of the sacred, analyzing empirical data concerning Syrian Muslim women's perception of Islam regardless of their educational level. Such an interpretation is to be a meaningful exercise to women living in the post-modern era and to produce an action plan for the Muslim woman to regain her identification with Islam. One of the Quranic intentions in entrusting human beings with individual rights and responsibilities toward themselves, each other, and the universe is to bring a balance between the sexes. The interpretations of these rights and responsibilities, therefore, need to stem from efforts to exact the balance between polarized perspectives that have dominated, for instance, the fields of Muslim women's studies and of human rights activism.
The strategic implications of this chapter lie in : (1) presenting a pedagogical paradigm to rethink and to act within the balanced perspective of Islam and its primary source, the Quran, away from the many layers of "taqlids" (following precedence) and from Western rationalization of Islam, (2) facilitating for Muslim women the strategies to realize their identity and to re-learn Islam in its clear, transforming meanings, and (3) interpreting human-rights activists' concerns within the Quranic concerns for a just human society, where justice means balance and fair play in the order of things, and a sustainable change of women's role.

title: Vicegerency and Gender Justice in Islam

This is a pre-copyedited version of an article accepted for publication in the edited book Islamic Identity and the Struggle for Justice following peer review. The definitive publisher-authenticated version is available through the University Press of Florida: http://www.upf.com/book.asp?id=BARAZS96. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#2This chapter summarizes Islamic view of life as a system and analyzes some implications of this system for family and male-female relationships. It is necessary, therefore, to replace the conceived notion that Islam is a religion limited to the ritual acts of worship (the five pillars) with the affirmation that Islam is a system designed for a purpose, and that this system is either accepted as a whole, understood within its ontological worldview, and acted upon within its components, or its practice may not be total. It is as important to understand that one cannot be operating partially within this system and still claim it as the base of operation. That is because whenever something is not accomplished according to what the system was designed to achieve one cannot discredit the system for not fulfilling its goals. One might understand the reason(s) that have lead to the unexpected results, rather, by exploring the steps that may have been missed during the application.

I am proposing that Islam as a system or an ideology has a central concept (or an essence) around which certain principles (or secondary and tertiary concepts) are built. These principles vary in their priority depending on their closeness to objectifying the central concept. The closer they are, the higher value they should be given and the more consideration they should receive in application of the system. Then on the outer circle (of the imaginary diagram) there are the auxiliary hypotheses (or the manifestations) which, if were appropriated within the framework of the central concept and with the essence of the principles as the base, will achieve the intended results (or the outcome) of the system.
The focus of this paper is on the Islamic principle of al-Khilafah (vicegerency of human beings to Allah as the Only God and the Supreme Guide), its social implications for the family, and where and how its manifestations may have been mistaken for its essence. Al-Khilafah is the purpose of the Islamic system, that is, fulfilling the purpose of creation and the will of Allah through human morality. The first part of the argument is that the principle of al-khilafah has been generally understood by Muslims and non-Muslims alike, and has been practiced by the majority of Muslims on its manifestation level and not at the essence level of the principle. Furthermore, the perception (conception and practice) of this principle has been generally outside the Islamic ontological view and without consideration of the central concept of Islam, Tawhid (the Oneness of God and humanity).
The second part of the argument will be stated as follows. Unless scholars, Muslims or non-Muslims, who are concerned with the study of Islamic family realize the different conceptual levels of the Islamic system, understand the variation in the implications of the different conceptualizations, and use the central concept as the epistemological base, their attempt to understand or prescribe solutions to injustice in male-female relations in the Muslim family will fail. Also, as long as Muslims are practicing the principle of al Khilafah and its social and political implications on the manifestation level only, they will not fulfill that principle nor the central concept of Islam, Tawhid.

This paper is intended to summarize and complement the two reports prepared by Bawab et al., the linguistic and technical team from The Higher Institute for Applied Sciences and Technology (HIAST) headed by Dr. Muhammad Mrayati of the Scientific Studies and Research Center (SSRC) in Damascus, Syria. The first, entitled "PC-Based Conjugation of Arabic Verbs," was presented at the Arab School of Science and Technology's Second Spring Session on Information Technology and Applications, sponsored by the United Nations Industrial Development Organization and SSRC in May 25-31, 1992. The second (in Arabic), entitled "al Nidham al Sarfi al Nahawi li al `Arabiyah bi al Hasib (Computerized Conjugational and Syntactical System of Arabic)," was presented at the Second Conference on Arabic Computational Linguistics in Kuwait, November 26-29, 1989.
The objective of this paper is twofold. One, to provide some suggestions concerning the educational applications of the Expert System (Nidham Khabir) and one of its sub-program, the PC-Based Conjugation of Arabic verbs . During my visit to the SSRC in January 1993, I was asked by the above team to develop these suggestions, based on my practical introduction to the system in addition to reading the above two reports. Both, through the practical demonstration of the system by the team following prior discussions of the linguistic groundwork and information technology that underlie the system, and throughout the reading of the reports, I felt a need to make this work known to all users of Arabic. Thus, the second objective is to share this significant achievement of the Syrian team with Arabic linguists, Teachers of Arabic and scholars of Arabic and Islamic studies.

title: Particularism and Multi-Cultural Education: Experience of Muslims in the United States
abstract: Copyright 1993, The Islamic Academy - Cambridge.
This is a pre-copyedited version of an article accepted for publication in the edited journal Muslim Education Quarterly following peer review. The definitive publisher-authenticated version is available through the

Islamic Academy - Cambridge. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#4An elementary school Muslim girl responded to her mother with the phrase, "BUT MOM, ALL MY FRIENDS DO THAT! WHY CAN'T I?" questioning the need to be different every time the mother said "No" to an activity the girl wanted to join neighborhood boys and girls in doing. The mother often contradicted herself and allowed her daughter to play because she was not able to explain the rationale for being different. The mother's spontaneous "No" response comes from the fact that in her home Islamic culture, children's activities are not usually separate from those of the family. Also, children rarely played in sexually heterogeneous groups where she was raised (the Indian subcontinent). Under the daughter's persistence, the mother gave permission, rationalizing to herself that a bicycle ride or video game with the neighborhood children would not affect the "Islamic" identity and values of her daughter. The mother rarely interacted with the parents of her daughter's playmates. She hardly knew who the playmates were or who supervised the play. Her understanding of these neighbors' values and worldview came only from what she saw manifested in their external behavior and in the norms of the society at large. The mother had contacts mainly with other mothers from her country of origin.

When the young girl reached puberty, her father, who rarely participated in decision making concerning his daughter's upbringing, told the young girl that she was to dress differently, she was no longer to have unnecessary conversations with boys, and she could no longer join in free play with her friends. The girl resisted her father's orders, and the mother supported her discreetly against the father's wishes. The mother thought that the father was being harsh and that there was no need to set such strict rules to ensure that the girl would develop the "Islamic" manners and the understanding of the "Islamic" religion as she, the mother, had been practicing it.

When the girl became a high school student, she took swimming as one of the sport activities required in the physical education course. She did not realize that close contact with the opposite sex, particularly in immodest clothes (a bathing suit in the presence of the opposite sex), violates a basic precept of the Islamic principle of modesty.

title: Islamic Education in the United States and Canada: Conception and Practice of the Islamic Belief System

This is a pre-copyedited version of an article accepted for publication in the edited book The Muslims of America following peer review. The definitive publisher-authenticated version is available through Oxford University Press: http://www.oup.com/us/catalog/general/subject/ReligionTheology/Islam/?view=usa&ci=9780195085594. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#4This study examines the way immigrant Muslim parents and their offspring perceive Islam and view its practice in the context of the Societies of the United States and Canada.

Historically and at present, the worldview of North American Muslims has generally differed from that of other groups who are either natives of or immigrants to North America. Yet not until recently has any substantial research been done on the presence of Muslims in North America let alone on their learning patterns or the role of differing worldviews in the education of their children.

Muslims may not be considered a minority ethnic group because they neither have the characteristics of the term minority ethnic nor Constitute a single linguistic, cultural, or socioeconomic group. Study of Muslims simply as minority ethnics or national groups will not help in understanding the variations in their attempts to maintain their Islamic identity. That is because, as Abdo A. Elkholy notes, "As Muslims in America are being assimilated, as Arabs, Turks, and other ethnic groups, many do not see the religious wrong in mixed

marriage."
Elkholy's observation relates to communicating Islam in North America on two levels. The first level is the way Muslims perceive themselves and hence identify with (a) Islam as a way of life, (b) Muslims as a religious group with which one may affiliate, or (c) nationality/ethnicity as an identity given to the Muslim subcultures by Western colonizers. The Muslim's perception of his/her own identity is the cornerstone in his/her ability to adjust to the new environment while maintaining the basics of the Islamic belief system and to transmit that system to the next generation in an integrative manner.
This perception of identity determines whether one's response is assimilation, integration, or withdrawal. The second level pertains to the realities of the North American pluralistic societies and their implicit and explicit demands for individual conformity to societal "norms." North American societies are established on a secular value system. They may allow for different religious practices, in the narrow sense of the word, but may not allow for ideological and epistemological differences. Therefore, Muslims will be assimilated as subcultural groups (Arabs, Turks, etc.) despite vigorous attempts by Muslim leaders and organizations to maintain the Islamic identity.
These leaders have failed to recognize that assimilation will persist as long as people's identity is in a state of confusion between ideological (Islamic), religious (Muslim), and ethnic (Arab, Turks, etc.) attachments. The clarity or confusion of one's identity is the key to the variation in Muslims' assimilation. The degree of Muslims' religiosity, as suggested by Elkholy, is only a part in the question of identification. The effort of any Muslim community in North America to formulate an educational program that will transmit the Islamic cultural and ideological heritage to its children is viewed here more as a conceptual than a socio-anthropological problem.

title: Parents and Youth: Perceiving and Practicing Islam in North America
abstract: Copyright 1991, Alberta University Press.
This is a pre-copyedited version of an article accepted for publication in the edited book Muslim Familes in North America following peer review. The definitive publisher-authenticated version is available through Alberta University Press: http://www.uap.ualberta.ca/UAP.asp?lid=41&bookid=162. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#4 This chapter examines how some Arab Muslim youth and families in North America perceive themselves both as Arabs and as Muslims in the context of Canadian and United States societies. Parents are concerned with how best to transmit the Islamic ideological and Arab cultural heritage to their children. One of their problems derives from differences among Arab Muslims, who come from varied national origins and hold several interpretations of the Islamic view, not all of which are based on the Qur'an; as a result they also have different nationalistic attachments to their understanding of Arab heritage. A second problem arises between immigrant parents and their American-reared children. The children may participate in American culture to a greater extent than their parents, and they are constantly faced with the conceptual need to accommodate potentially conflicting points of view. Effective identity transmission requires the determination of the nature and extent of the different interpretations held by parents and their children and of the way these interpretations are reflected in their practice of Islam and association with the Arabic heritage.

title: Acculturation of North American Arab Muslims: Minority Relations or Worldview Variations
abstract: Copyright 1990, Institute of Muslim Minority Affairs.
This is a pre-copyedited version of an article accepted for publication in the edited Journal of the Institute of Muslim Minority Affairs following peer review. The definitive publisher-authenticated version is available through Institute of Muslim Minority Affairs: http://www.imma.org.uk/jmma.htm. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#4The main objective of this study is to explore the concept of minority/majority relations as the underlying assumption in studying empowering and adjustment strategies of North American Arab Muslims (NAAM). That Muslims are viewed as Arabs, Turks, Pakistanis, etc. is a hindrance to the understanding of the metaphysical and epistemological variations between the Islamic and the Western secular worldviews, on one hand, and the Islamic and the Arabic acculturation processes, on the other. Attempts to develop an integrative Islamic education program for Arab Muslims, therefore, have failed mainly because NAAM view themselves, and are being studied, as an ethnic minority rather than a "mainstream" majority. Based on this view, "Islamic" education programs have emphasized the ideals of the Ummah (the Islamic State) and the teaching of Arabic as the empowering strategies for the Arab Muslim minority. Acculturation practices among Arab Muslims, however, have emphasized ethnic preservation strategies that do not empower these groups either with the privileges of recognized minorities (i.e., classified racial and socioeconomic groups such as Afro-Americans and Hispanics) or with the acceptance by the prevailing "color prejudice" majority. Results from the author's doctoral research project indicate that the majority of immigrant Arab Muslim adults have resolved this conflict between ideal and practice by separating their religious, ethnic, and secular societal lives. These adults also view the transmission of the Islamic/Arabic identity only as a transmission of religious teachings and ethnic traditions. The youth, on the other hand, remain unclear of their group identity and of its association with the larger society . The findings and the implications of this study are applicable to any group of people, Muslims or non-Muslims, who share a different worldview from that of the larger host society.

title: The Education of North American Muslim Parents and Children: Conceptual Change As a Contribution to Islamization of Education
abstract: Copyright 1990, Association of Muslim Social Scientists. http://www.amss.net/ See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#4Four points of investigation are needed to develop a theoretical model for the Islamization of education in the context of the pluralistic societies of N. America. (1) The dynamics by which Muslims have arrived at a view of Islam that causes them to practice it in a particular way, (2) the variation in the conception and practice of Islam between the immigrant parents and their offspring, on one hand, and between the immigrant and the native Muslims, on the other, (3) the extent to which Muslims perceive the Western secular view to be in conflict with their own view as reflected in their adjustment process and in their transmission of the "Islamic" heritage, and (4) the ability of the educators to design programs that can reconcile the conflict, apparent or real, between the Islamic and the Western views of life and education.
The underlying assumptions are that in addition to the historical development of the Islamic conceptual ecology and its secular Western counterpart, the Muslims of N. America also have a distinct history and a living experience to be investigated. Moreover, understanding the subject matter, Islam, requires an investigation of the documents pertaining to it, namely al-Qur'an and the books of hadith. This investigation is a must for understanding (1) the variation in meanings given to the present ideas, (2) the relative stability or change in the conception and practice of the Islamic tenets over time, and (3) the new conception(s) and approach(s) to "Islamized education."

The aim is to determine (1) the Muslims' synthesis of all the factors (such as religion and faith, moral and cognitive development, socioanthropological demands, and pedagogical approaches) that have been secularized because of specialized approaches to human learning, (2) the level and type of awareness that the faithful individual has about human and revealed knowledge, (3) whether the individual is operating within the central concept of Islam, i.e., Tawhid (Oneness of God as the Source of knowledge and value), or within another concept that is outside of Tawhid that entails duality and secularity in education, and (4) whether or not curriculum designers are able to distinguish between Islam as the underlying value system and Islam as the subject matter as well as the encompassing social milieu.
The curriculum specialist developing programs for Muslim communities in pluralistic societies must keep in mind (1) the governing ideology (the belief system) and the authority (experts) who determine the type of "Islamic" knowledge, (2) the level of the experts'/learners' awareness of the relationship between their own conception of the ideology and the forces that govern their drawing of values and codes and, hence, the practice of the faith, and (3) the structure and means by which he or she can move from the Islamic philosophical system into an Islamic pedagogical system.
Three basic conditions, therefore, are essential for a program design and for a theoretical model of the Islamization of education: (1) to understand the Islamic educational pedagogy vis-a-vis the Western pedagogy, (2) to adopt an eclectic view of curriculum and to incorporate it with the reconstruction of religious thought in Islam(3) to keep in mind the epistemological, familial and contextual compositions and their effect on attitudinal and conceptual change of the learner.

title: Arab Muslim Identity Transmission: Parents and Youth
abstract: Copyright 1989, Association of Arab-American University Graduates. This is a pre-copyedited version of an article accepted for publication in the edited journal Arab Studies Quarterly following peer review. The definitive publisher-authenticated version is available through the Association of Arab-American University Graduates: http://www.emich.edu/asquarterly/. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#4Effective Islamic identity transmission requires determination of the nature and extensiveness of the different interpretations held by parents and their children and the ways these interpretations are reflected in their practice of Islam and association with Arabic heritage. Fifteen Arab Muslim families of varied nationalities were interviewed as part of a larger study on Muslims in North America. The findings indicate that parents and youth have significantly different perceptions. Parents have higher levels of perception for the central concept of Islam, i.e., Tawhid (Oneness of God), but only in abstract form, whereas youth tend to emphasize some of the auxiliary concepts of Islam, i.e., human-interrelation behavior, but in the context of Western values. This may explain (1) difficulties parents encounter in effectively transmitting the Islamic belief system and/or the Arabic heritage to their children, (2) the youths' inability to distinguish between the Islamic/Arabic and the Western systems on the ideological level, and (3) the youths' confusion concerning their roots and history.

title: An Ethical Theory of Action Research Pedagogy
abstract: Copyright 2006, SAGE Publications.

This is a pre-copyedited version of an article accepted for publication in the edited journal Action Research following peer review. The definitive publisher-authenticated version is available through SAGE Publications: http://arj.sagepub.com/cgi/content/abstract/4/1/97. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#5The theory of action research (AR) pedagogy presented in this article is, at its core, ethical in nature. For teaching, learning, and evaluating AR, the theory's goal is to increase individuals' capacity to act on their own behalf and preventing themselves from becoming an authoritarian expert. Achieving such an increased individual capacity requires the integration and deployment of multiple dimensions of ethical principles and understanding their implications for the ethics of AR pedagogy. An integration of Ibn Miskawayh's Islamic philosophy of ethical pedagogy, Iris Young's theory of justice, Greenwood and Levin's criteria for ethical participation, and my own model of participatory action research evaluation that is central to the learning process constitutes the basis of this ethical theory of AR pedagogy.

title: Evaluation Model for an Undergraduate Action Research Program
abstract: Copyright 2004, The University of Victoria.
http://www.educ.uvic.ca/ See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#5In this paper, we will articulate how the model of "evaluation being central to learning, teaching, and living Action Research (AR)" has evolved. This model was developed as part of the Bartels Undergraduate Fellows Program at Cornell University who are collaborating with surrounding communities.
The model is centered on the Fellows' participation in the reflective analysis of their self-generated data. The goal is to learn about AR by actually using its tools to understand their own learning process and how their acquired learning behaviors are, to a certain extent, stand in the way of their being able to help their community partners solve issues of joint interest. These community partners are interested in finding sustainable and fair solutions to issues of North American Indian women's health, hazing, stereotyping, homelessness, youth conflicts and empowerment, incarceration, migrant farm workers, and community development that have been reinforced by the passive learning/teaching/research approach. This reflective view is what we hope will 'click' among the fellows when they examine their own self-evaluation data.
From this, we hope to learn how:
(1) the undergraduate seminar instructional process is imparting the epistemology and methodology of Participatory Action Research with the participating Fellows, and what have been limiting or facilitating the process, and
(2) how the university organizational structure is providing support or limitation to the faculty and staff who mentor the participating Fellows in service learning.
In other words, we hope to understand how best to realize AR in a participatory learning environment that is based in a participatory community development.

title: Future of Social Sciences and Humanities in Corporate Universities: Curricula, Exclusions, Inclusions, and Voice
abstract: Copyright 2001, Nimat Hafez Barazangi. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#5During three preceding sessions of the Institute for European Studies (IES) Topical Seminar, three themes were discussed: (1) The university as a corporation, focusing on faculty involvement

and partnership with the corporation and the corporate world beyond the university, (2) the students as inheritors of culture and the university as the means of perpetuating cultural norms, and (3) the economic base of higher education.
In my focus on the curriculum, I am basically looking at the philosophical, ethical, and pedagogical dynamics of all the above elements when mapping and disseminating knowledge. I am also looking at how knowledge itself, a main asset of the university, is manipulated between research, teaching, and learning by the old and new guard of academia. Though the three essays (Barazangi, 1993; hooks, 1994, Middleton, 1993) being analyzed under the curriculum theme were written for different cases and from different worldviews, they share the same historical context. A time when the New Right movements were back lashing at the different cultural groups, including women, as these groups voiced their concerns about curricular inclusions and exclusions, these reactions were manifested in the multicultural vs. mainstream curricula, in the affirmative action admission and testing practices, and in social welfare policies.
The contemporary context consists, in addition, in recent emphases by funding agencies on educational components in research proposals even by NSF, especially in K-12. Residential learning among college students, is replacing ethnic-based dorms or language houses. Yet, the old philosophy of dichotomized subject matters and fields of studies still prevails in recent discussions of liberal arts curricula. A recent report by the Curriculum Committee of the Cornell College of Arts and Sciences still classifies reasoning skills into quantitative and qualitative, with an add-on of moral reasoning. Furthermore, engagement in learning is mainly still treated as a practical skill for the arts and sciences and not part of their main mission, and so on.

title: Is Language the Object of Literacy among United States Female Adult Learners?
abstract: Copyright 1999, Language and Literacy Spectrum, Journal of The New York State Reading Association.
This is a pre-copyedited version of an article accepted for publication in the edited journal Language and Literacy Spectrum, a Journal of The New York State Reading Association, following peer review. The definitive publisher-authenticated version is available through The New York State Reading Association: http://www.nysreading.org/Publications/index.html. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#5We present a case-study of adult females becoming "literate." Low income female learners in Adult Basic Education (ABE) and recent immigrant learners in English as a Second Language (ESL), and their teachers in Central New York State were involved in a Participatory Action Research (PAR).
The goal is to present conceptual and attitudinal issues of adult literacy in the United States (US), including ESL and feminist pedagogy. The results suggest that language literacy by itself may not lead to a sustainable autonomous individual and group development. We discuss literacy within attitudinal change about female learner's self-realization vis-a-vis her productivity and social mobility.

title: Book Review of: Claiming Our Rights: A Manual for Women's Human Rights Education in Muslim Societies by Mahnaz Afkhami and Haleh Vaziri
abstract: Copyright 1997, Association for Middle East Womens Studies.
This is a pre-copyedited version of an article accepted for publication in the edited AMEWS Newsletter following peer review. The definitive publisher-authenticated version is available through The Association for Middle East Womens Studies: http://www.amews.org/index.html. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#6The purpose of Claiming Our Rights: A Manual for Women's Human Rights Education in Muslim Societies by Mahnaz Afkhami and Haleh Vaziri (Bethesda, MD: Sisterhood Is Global Institute, 154 pp., 1996) is "to facilitate transmission of the universal human rights concepts inscribed in the major international human rights documents to grassroots populations in Muslim societies." It is an invaluable contribution of the Sisterhood Is Global Institute (SIGI) and a much needed beginning to educate Muslim women's of their rights in Islam.
Its themes, derived from the mission statement of Platform for Action of the Beijing Conference (iv), are necessary for individuals who are already aware and started to question the discrepancy in the practice concerning their human rights. What is needed in the methodology, therefore, is a section that will facilitate awareness-raising as the initial step that will instigate women to start questioning and dialoguing about the different themes. This methodological adjustment would have been addressed intuitively had the authors, as well as the scholars and practitioners who were consulted, considered an important element in their explanation of the meaning of "Shari`ah" under the section "Major Premise."
The authors, despite their utmost care not to "impart the truth" but to "facilitate dialogue" (Mahnaz Afkhami's letter of introduction) have over-looked the fact that human knowledge and action are affected by the human belief system. Whether we call it "religion," "faith," or "worldview", such a belief system composes an important component of one's prior knowledge. This prior knowledge either makes an individual aware or dormant concerning abuses of her human rights. It also makes an individual either accept or reject the "central premise of this human rights educational model that there is no contradictions between human rights and Islam." (v)

title: Book Review of: Qur'an and Woman by Amina Wadud-Muhsin
abstract: Copyright 1994, Journal of Islamic Studies, Oxford University Press.
This is a pre-copyedited version of an article accepted for publication in the edited publication Journal of Islamic Studies following peer review. The definitive publisher-authenticated version is available through Oxford University Press: http://jis.oxfordjournals.org. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#6Wadud-Muhsin's book is a welcomed addition to Islamic studies scholarly work as well as to the list of readings in Women's Studies and Islamic Studies courses. The media and the popular culture

literature in America and Europe are not the only biased group in portraying women in Islam as "oppressed" and that their liberation can take place only outside Islam. Contrary to my trust in the impartiality of educational institutions, I am finding that such institutions are more inequitable when it comes to scholars who address the "Muslim woman question" from within the framework of Islam. I was surprised, for instance to find that only one theological seminary library in the entire United States has obtained this book, even though many universities, including my institution, have a long list of recent publications on Muslim women.

title: Book Review of: The Rights of Women in Islam by Asghar Ali Engineer
abstract: Copyright 1994, Journal of Islamic Studies, Oxford University Press.
This is a pre-copyedited version of an article accepted for publication in the edited publication Journal of Islamic Studies following peer review. The definitive publisher-authenticated version is available through Oxford University Press: http://jis.oxfordjournals.org. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#6Engineer's book though not unique in its purpose, the defense of women's rights in Islam, is different from other books that deal with the same subject in its approach to the "question of women." By attempting , in this book, "to separate what is contextual from what is normative" and to "recapture the original spirit of Qur'anic laws with regard to male-female relationship," the author hoped to equip Muslim feminists with a powerful weapon in their fight for equal status with men (p. vi). The author is to be commended for this unprecedented courage to contradict what has been the customary views on women's rights in Islam, whether by Muslims or non-Muslims. His documentation from the Qur'an, Hadith and early Islamic history of issues like sexual equality, marriage, divorce, and others that have been only presented from the Muqallidun's (those who follow the foot-steps of ancestors) points of view is a major step by a Muslim male scholar.

title: Between the Post-ethnic and the Unique: Exclusion of American Muslim Women and Policy-Making
abstract: Copyright 2007, Nimat Hafez Barazangi. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#9Muslim women are treated in a similar manner by the media and the globalization political process. Because of this fusion between sensational media reporting and policy-making, combined with compartmentalized scholarship (area studies, Islamic studies, women's studies) and activism (Muslim vs. Western), a Muslim woman is often not viewed as an autonomous entity that could and should be involved in policy-making. This pattern of ignoring Muslim women's political participation is repeated even in the United States. With the exception of a few, the majority of American Muslim women of varying backgrounds and educational levels are neither involved in the domestic nor in the international affairs of the US. Hence, the issue is: how is it possible for the estimated three million American Muslim women to become a political reality to further the US democratic policy, the US Muslim political and legal rights, or Muslim women's human rights all over the world.

title: The Equilibrium: Issues of Islamic Education in the United States
abstract: Copyright 1998, Religion and Education, Nimat Hafez Barazangi.
This is a pre-copyedited version of an editorial accepted for publication in the edited journal Religion and Education following peer review. The definitive publisher-authenticated version is available through Religion and Education: http://fp.uni.edu/jrae/islamicissuetoc.htm. See also: http://www.eself-learning-arabic.cornell.edu/publications.htm#1The theme of this special edition of Religion and Education (R&E) on "Issues of Islamic Education" is taqwa. Taqwa is an Arabic word often translated oversimply as "piety," but which bears the meaning of "a conscious balance between the individual, the society, and the limits set by Allah or God as the source of value and knowledge". Since I was asked to be guest editor of this edition, three overarching issues have been formulating my thinking about it, from selecting the theme to the significance that this edition of R&E may have for the debate over education in the country as a whole.
The first issue is how to achieve a balance between the belief systems of individuals (often referred to as religion or philosophy) and this country's universal schooling system which has traditionally intended, to a large degree, to meld diverse individual views into the "common-ground" of a "pluralistic" social framework.
The second issue is questioning the efficacy of "teaching about religion" and "teaching a religion." This issue comes out in particularly sharp relief in teaching about Islam as a belief system, and about Muslims, in a "neutral" manner when many teachers have little or no knowledge of Islam, and what they have too often represents an inaccurate picture.
The third issue, which is the core of this edition, is how to introduce a discourse on "Islamic education" when females have traditionally been perceived as lacking the full privilege to interpret Islam. The centrality of Muslim women's and girls' education and acculturation (Barazangi and Kahf articles) to Islamic education may seem contradictory, and perhaps difficult to understand by those whose knowledge of Islam is limited to the perception that males are the only "legitimate interpreters" of Islamic texts or the perception that females are "oppressed by their patriarchal religion."

title: Instances of Instantiation: Distinguishing between Subjective and Objective Properties
abstract: This thesis explores the prospects of a distinction between subjective and objective properties in terms of how they are instantiated. While there are many ways in which the subjective can be separated from the objective, the one that interests me here is the difference between properties instantiated subjectively and properties instantiated objectively. The idea is that in some cases what makes it so that object o has the property p is what a thinking subject thinks of it or how she reacts to it, while in other cases what makes it so that o has p has nothing to do with what the subject thinks or does. In the first kind of case, the instantiation of the property is mind-dependent, or subjective, and in the second kind of case the instantiation is mind-independent, or objective. I examine ways to draw a distinction between subjective and objective properties in this sense and defend the possibility of such a distinction against conceivable threats. I then go on to arguing that instead of sorting properties into two groups, subjective and objective, it is more fruitful to think of them as on a continuum ranging from entirely subjective to entirely objective. While there may be cases of properties that are entirely objective, i.e. instantiated only objectively, finding entirely subjective properties if more difficult. Candidates for subjective properties do not seem to be exclusively subjective; i.e. they are instantiated objectively to some extent. I use color as a paradigm case to argue for my account of properties whose instantiation is partly objective and partly subjective. I then go on to arguing that all sensory properties should be treated as color in this respect.

title: Understanding the Role of Human Dynamics in the Practices of Cleveland Area Landscape Architectural Firms
abstract: This thesis aims to discover, understand, and evaluate the contemporary client and user involvement practices of landscape architects in the Greater Cleveland area. The research used narrative interviews with firms and their clients to answer the following questions:
1. Do landscape architects correctly interpret their clients? needs?
2. Are clients? needs incorporated into designs?
3. Are clients satisfied with landscape architectural services?
4. Do landscape architects involve users on a regular basis?
5. Is there a set of best practices to adopt when working with clients?

The results showed that landscape architects focused on understanding the needs of their clients from the beginning of the design process through one-on-one communication with them. This input was incorporated into designs to the satisfaction of the clients. Landscape architects felt that part of their job was to educate clients about good design. This allows their practical and creative input to combine with the client?s producing a design that satisfies their needs and holds up over time. Clients appreciate the practical recommendations and high level of communication that the landscape architects offer.
Users do not participate in the design process on a day-to-day basis, although most firms work with them sporadically. The methods for working with them are not well defined by the interviewees.
Both client and user involvement is limited by budget constraints, project type, and client wishes.

title: Landscape Symbolism of Imperial Rome: Reflecting the Governmental Changes from the Republic to the Empire
abstract: This work presents research on the symbolic intent of public space in Rome during the fall of the Republic, (61 ? 2 BC). The thesis focuses particularly on the three largest public developments occurring during this time period: the Theatre Complex of Pompey, the Forum of Caesar, and the Forum of Augustus. The political organization of Rome was changing during this time period, slowly transitioning from a representative democracy to an imperial dictatorship. Certain elements of the three public spaces that were created at this time symbolize these political transformations. Providing detailed design analysis of these areas will help in understanding the use of symbolic attributes of the public landscape. The specific elements to be studied are: location, orientation, axes, and scale.

title: Formative Evaluation of Massachusetts Audubon Society?s Coastal Waterbird Program
abstract: I conducted a formative evaluation of the Massachusetts Audubon Society?s Coastal Waterbird Program (CWP). Specifically, I used document analyses, interviews, and a mail census of CWP staff to assess the appropriateness and adequacy of CWP design and implementation actions. I identified that the Theory of Planned Behavior (TPB) could be used as an appropriate social science foundation to improve the program

design and the identification of additional implementation actions. Most implementation actions seemed to focus on the monitoring of nest success and fledging rate of protected bird species that nest on beaches and reacting to public behaviors that are disturbing to these birds. According to TPB, additional benefits likely could be achieved by developing implementation actions focused on proactively engaging the public to prevent disturbing behaviors before they occur. Survey results indicated that field staff already engage in proactive actions despite not being trained extensively to do so. In addition, staff held substantially more positive evaluative beliefs about proactive interactions than reactive interactions. Rather than identifying problems confronting the CWP, these results identify opportunities that can be built on to improve the program.

title: Retention of logging debris to reduce deer browsing and promote forest regeneration
abstract: One of the most important species in northeastern forest ecosystems is the white-tailed deer (Odocoileus virginianus). Browsing by these herbivores can influence patterns of forest regeneration following a timber harvest. Logging debris, or ?slash?, has the potential to inhibit deer browsing and enhance forest regeneration in a cutover area. At two heavily logged sites in the Arnot Forest, NY, study plots containing experimental seedlings and natural vegetation were created in May 2004 and monitored thru November 2006. Each plot received one of three treatments: open - cleared of logging debris; tops ? tree tops and debris-covered; or fenced - cleared of debris and fenced to exclude deer. Levels of deer browsing in experimental seedlings and natural vegetation, tree seedling growth, and natural vegetation richness, were compared among these treatments. We found significantly higher deer browsing on experimental seedlings ($p = .0053$) and palatable herbaceous vegetation ($p = .0094$) in open plots, than tops-covered or fenced plots. Cumulative deer browsing negatively correlated with mean experimental seedling height at the plot level ($p = .0296$), resulting in higher black cherry (Prunus serotina) seedling growth in protected fenced and tops treatments. Additionally, logging debris was found to benefit common management objectives, such as herb richness and relative abundance of desirable timber tree seedlings. We conclude that logging debris left in place after a forest thinning can effectively inhibit deer browsing and promote forest regeneration. The degree of protection afforded by tree tops was intermediate between unprotected and fenced areas. The minimal effort and cost associated with this technique would make it highly preferable to constructing fences to improve regeneration. As white-tailed deer become increasingly overabundant, alternative options for the sustainable regeneration of forests are necessary; the post-harvest retention of logging debris in situ provides such an alternative.

title: Macroinvertebrate colonization of invasive Fallopia x bohemica leaf litter in a temperate stream
abstract: We compared macroinvertebrate communities on leaf packs made of recently senesced leaves of native Quercus and Acer, and invasive Fallopia x bohemica. Leaf packs were left in Cascadilla Creek, a third-order temperate stream in central New York, U.S.A., for 7, 14, 28, or 56 days. After we removed them from the stream, we examined the leaf packs for biomass loss and invertebrate richness and abundance. While we expected to see a significant difference between leaf types, which would indicate a cascade effect of invasive vegetation on higher trophic levels, little variation was actually seen. The results of this study suggest that localized effects of F. x bohemica on invertebrate communities in streams are quite small if the invasive component represents only a small percentage of the total biomass of the system. Leaf breakdown rates also did not differ significantly between the invasive and either of the two native leaf types. We observed

larger numbers of predators on leaves of F. x bohemica than on either of the native leaf types, which may impact leaf breakdown and consumer activity over a longer study period, but what we have seen so far is still inconclusive. Further study will have to better simulate true invasion conditions where native vegetation is not available to invertebrate communities, and incorporate a full season of leaf breakdown.

title: William J. Hamilton, Jr. of Cornell, The Man and the Myth
abstract: William J. Hamilton, Jr. was a prominent Professor of Mammalogy who was beloved by his students and peers. Bill entered Cornell as an undergraduate in 1920 and stayed until his death in 1990. Professor Hamilton helped found the Department of Conservation in 1947, which was the precursor to the Department of Natural Resources. During his 33 years as a professor, he directed 60 graduate students and was on the thesis committee of 150. Bill was a meticulous note taker, and encouraged his students to do the same. He was a great naturalist whose specialty in mammalogy only exceeded his knowledge in other fields of natural history. Throughout his life he supported the study of "Backyard Biology" ? the belief that scientific wonders could be discovered at your own doorstep. He was an avid gardener who introduced many garden species to New York State. ?Wild Bill?, as he was known, was famous for his tall tales and practical jokes. Oftentimes, this jesting was focused on teaching his students a lesson, or exposing the faults in that person?s knowledge. His academic honors included publishing over 230 scholarly articles, serving as the president of the American Society of Mammalogists and as the president of the Ecological Society of America. His textbook, Mammals of Eastern North America, became the textbook of choice for decades and to this day has remained a critical resource for students. Through personal interviews, archival research and contact with the Hamilton family, the author has created an abbreviated biography.

title: The role of pre-mastication in the evolution of complementary feeding strategies: a bio-cultural analysis
abstract: Human milk is a poor source of iron. At birth, the newborn is well endowed with iron stores, which are adequate to meet his/her needs for the first 4-6 months of infancy (WHO March 2001), and iron deficiency is rare. On the other hand, iron deficiency is prevalent among infants between 6- 12 months of age, particularly in developing countries, and iron supplementation during breastfeeding, and thereafter, is recommended, in addition to 6 months exclusive breastfeeding (WHO, 2002). If exclusively breastfed infants are becoming anemic by the time complementary foods are first being introduced, this raises a challenge to our assumptions about the nature of human bio-cultural evolution. Is the anemia of infancy normal or did usual feeding practices prevent it? As iron supplementation was not possible until recently, I hypothesized that exclusive breastfeeding was complemented by premasticated foods during our evolution as a hunting-gathering species. In other words, that iron deficiency in infancy is a recent problem in human society, which was previously prevented by premastication.
The goals of this research were to assess the prevalence of premastication in non-modern societies in order to determine whether (1) it was prevalent enough to support plausibly its role as a behavioral adaptation to prevent iron deficiency and (2) to determine whether the potentially detrimental effects of premasticated food were harmful enough to be selected against. This research involves several lines of investigation: 1) bringing together the evidence that iron deficiency is a common problem, which is now found in many different regions

of the world, 2) a cross-cultural study, using the Human Relations Area Files (HRAF) to obtain ethnographic data on the distribution and time depth of premastication in human societies, 3) a field research study in China, based on interviews conducted by University students, to examine the potential for serious under-reporting of pre-mastication in the ethnographic studies, 4) a review of the iron content of foods that are reported to be premasticated, and 5) a review of the scientific literature on the content of saliva.
In the HRAF analysis, 39 cultures out of 119 cultures (33%) that contain any information on infant feeding describe premastication as an infant feeding practice. Notably none of the ethnographies from China mention premastication. However, the field survey in China, with a sample of 104 elite college students, found that 63% (65 of 104) were fed pre-masticated food when they were infants, and those who received premasticated foods were more likely to be fed complementary foods earlier than those who did not. The survey findings support the notion that premastication tends to be under-reported in ethnographic studies. Although salvia has not been as extensively studied as breastmilk, the review of the biomedical literature suggests that it contains several potential positive substances from the perspective of infant health and fewer negative substances than are commonly assumed.
The results of the various lines of investigation suggest that pre-mastication has been a common practice in human societies, but has been significantly under-reported.
The potential dangers of increased infection that pre-mastication poses for infant health have probably been less serious than the disadvantages of not engaging in pre-mastication, which is a means of giving infants iron to prevent deficiency as stores begin to drop during the first semester of life. Therefore I conclude it is probable that pre-mastication was the behavior/cultural solution to the complementary feeding challenge in human societies, that it probably prevented the level of iron deficiency, which is common today in poor societies.

title: Development and Characterization of a Novel Concentrated Milk Product Using Membrane Filtration Technology
abstract: In recent years microfiltration (MF) technology has gained prominence in dairy industry due to its ability to separate virtually every major component in milk without causing major damages to its properties. Current shelf-stable concentrated dairy products often have brown off-colors and ?cooked? off-flavors due to heat-induced Maillard browning and whey protein denaturation that occur during sterilization.
MF was used in this study to develop a novel concentrated milk product depleted of most of its lactose (to limit Maillard browning) and whey proteins. Acidified skim milk was concentrated to 8x microfiltration concentration factor and then diluted 1:1 with distilled water and sterilized in cans to produce a microfiltered milk concentrate (MMC).
The MMC was characterized by its chemical composition, color, apparent viscosity, flow behavior, and storage potential. Furthermore, these characteristics of the MMC were compared with a concentrated dairy product, commercial evaporated milk (CEM).
The % (w/w) composition of the MMC was found to be 20.6% total solids, 13.4% true protein, 12.0% casein, 0.6% fat, 1.5% ash, 1.8% lactose and 0.7% whey proteins. It was comparable to CEM in total solids, greater in true protein, casein, and fat, and lower in ash, lactose and whey proteins. The MMC retained much more of the white color of HTST-pasteurized milk than the CEM. The apparent viscosity (~9.5 cP at 30?C) of the MMC was much greater than that of the CEM and the MMC was seen to be more pseudoplastic in nature ($n < 1$) than the CEM. The changes during 12-month storage were comparable between the CEM and MMC samples.

title: Molecular Evolution of the prfA Cluster in Listeria monocytogenes Lineage III Isolates
abstract: Listeria monocytogenes lineage III represents a diverse subset that is generally associated with non-human mammalian infection, although some isolates are capable of infecting humans. A cluster of virulence genes (prfA, plcA, hly, mpl, actA, and plcB), known as the prfA cluster, was sequenced in eleven lineage III isolates from food, animal, and human clinical cases, and analyzed in conjunction with forty previously sequenced isolates from lineages I (n = 18), II (n = 21), and III (n = 1). The lineage III isolates represent three previously identified lineage III subsets known as lineage IIIA, IIIB, and IIIC.
Evolutionary analysis identified intragenic positive selection in actA and plcA, and intergenic positive selection in the non-coding regions flanking hly. Positive selection in actA occurred in many positions previously recognized for their interactions with proteins involved in actin tail polymerization. Also, one positively selected site upstream of hly was located in its -35 promoter region. Additionally, horizontal gene transfer was recognized in actA, plcB, and mpl. The majority of events involved actA fragments transferred between lineages IIIA and II. Lineage IIIB did not partipate in any inter-lineage recombination events, but may have donated an mpl fragment to lineage IIIC. Neighbor joining phylogenies suggest that lineage III subsets IIIA and IIIC are monophyletic with lineage I, but that lineage IIIB is not. Therefore, due to its lack of horizontal gene transfer, and distant phylogenetic relationship to the rest of L. monocytogenes, lineage IIIB may represent a distinct subspecies.

title: Snow Distribution Patterns at Land Cover Boundaries in Tompkins County, NY
abstract: Since humans first began clearing land for agriculture, rural landscapes have become a complex mosaic of forests and fields. During winter, the borders between these two land use types become especially interesting as winds moving across fields entrain fallen snow and may redistribute it to the forest edge. Since snow depth can have serious implications for soil conditions and biogeochemical processes, I proposed to evaluate snow distribution at field- forest boundaries in Tompkins County, NY through a combination of techniques that address the degree of snow redistribution at a variety of scales. Continuous measures using time-lapse photographs taken along a field border from January to March 2007 were used to assess localized redistribution over a snow period. These observations revealed snow accumulation at the field-forest border particularly in areas where the grass in the field had been mowed. Manual measurements of snow depth across several field- forest borders throughout the county were used to estimate how much snow was redistributed to borders, on average, in the county. These data demonstrated that there are a number of factors affecting the extent of snow redistribution from fields to forest borders, but the phenomenon definitely exists. A rough extrapolation of our results suggests that 1.9% of Tompkins County?s snow accumulates at these boundaries (which comprise 1.3% of the county?s area). With the increasing fragmentation of landscapes, it is integral to understand physical processes such as snow drifting at forest edges so that we can then better comprehend the ecological implications of such occurrences.

title: The Destruction and Revival of a Neighborhood
abstract: This examination of what is apparently the oldest African-American and ethnically diverse neighborhood in the United States, Faubourg Treme, New Orleans, LA, follows the development of urban renewal and regeneration and transportation projects "gone bad" in the Treme neighborhood. These projects have been the major factor on the blight of the community. The faubourg is located in close proximity to both downtown New Orleans and the French Quarter (Vieux Carre) making it exploitable to city planners and the government as a place to service the downtown and French Quarter. These services included but were not limited to housing for service and working class employees and an interstate highway ramp. The goal of the transportation project was to make the tourist centers more accessible to tourist travel and the suburbs of New Orleans. The blight of this once vibrant neighborhood prompted questions, including how and why did the urban renewal and transportation projects cause massive amounts of displacement without replacement of residents? How does Treme retain its historical character as well as welcome reinvestment?

title: Local Minimum of Tropical Cyclogenesis in the Eastern Caribbean
abstract: The study has determined that a local, climatological minimum of tropical cyclogenesis exists over the eastern Caribbean Sea. This area, known colloquially by forecasters as the ?hurricane graveyard,? is located within the belt of tropical easterlies during most of the Atlantic hurricane season, which lasts from June through November. Tropical easterly waves emerging from the African continent usually follow a path through the Lesser Antilles and into the eastern Caribbean. GOES infrared satellite imagery shows that easterly waves frequently exhibit warming cloud tops and decreasing convection in an area bounded by the islands to the north and east, Venezuela to the south, and roughly 75 degrees longitude to the west. QuikSCAT derived surface winds during clear-sky conditions frequently show the presence of accelerating easterlies in the central Caribbean as part of the Caribbean Low-Level Jet (CLLJ). Analysis of the NCEP global reanalysis wind fields suggests the presence of an area of persistent low-level mass divergence in the eastern Caribbean. This implies a subsident regime that would weaken convection. Climatologically, this phenomenon reaches peak intensity in July, then shifts towards the east and weakens in the latter half of the Atlantic hurricane season. This is reflected by the local minimum of tropical cyclogenesis points in the National Hurricane Center?s best track data in the early part of the season. El Ni?o directly affects the strength of the CLLJ, and hence, is related to the intensity of the low-level divergence in the eastern Caribbean. The local minimum of tropical cyclogenesis in this region has important implications to operational forecasting, since the vast majority of tropical cyclones in the Caribbean eventually affect surrounding landmasses.

title: Staying Afloat in the Hospitality Industry: The Importance of Intercultural Communication
abstract: This study examines the importance of intercultural communication for career development in two segments of the hospitality industry, cruise and hotel. Three topics are explored: (1) the perceived relative importance of intercultural communication skills for career development, (2) whether differences exist between native and non-native English speakers in the importance assigned to intercultural communication, and (3) whether differences exist between cruise and hotel managers regarding the extent to which intercultural communication is perceived as important to career development.
The sample for the original study consisted of 77 cruise ship directors and 111 hotel general managers. All 188

participants completed a Likert-style questionnaire. The questionnaire was designed to collect information on the personal characteristics and skills perceived to be critical to managers? career development in the hotel or cruise industry. Demographic information was also collected. Descriptive statistics, Pearson Product Moment Correlations, Independent Samples t Tests, and content analysis were conducted. Analyses indicated that the respondents perceive intercultural communication to be moderately important in the hospitality industry, that non-native English speakers perceive intercultural communication skills as more important to career development than native English-speakers, and that cruise ship directors perceive intercultural communication skills as more important for career success than hotel general managers. In addition, the results suggest a need for hospitality practitioners to improve upon and hospitality educators to teach intercultural communication skills to facilitate the career development of hospitality managers. Future directions for research are also suggested.

title: Nice to Meet You: Deception in Initial Interactions
abstract: In this paper we describe an experiment comparing the production of lies in first encounters that took place face-to-face (FTF) or in computer-mediated communication (CMC: instant-messaging). Participants reviewed their conversations and retrospectively identified deceptive statements. While the overall incidence of lying did not differ across conditions, the rate of deception per information exchanged was significantly higher in CMC. The characteristics of the lies suggest that the content and severity of lies do not vary substantially across media.

title: Social Support and Family Status as Influences on Perceptions of Health Risks and Information-Seeking Behavior: A Case of New York State Teachers
abstract: Numerous studies have indicated the importance of social support to health; those who are less socially integrated are psychologically and physically less healthy, and have higher mortality rates. A primary social support system is the family, which may be further characterized by the marital relationship and the parental relationship. This study examines one mechanism by which the influence family status, social networks and social integration may alter the perception of risks and information-seeking behaviors. If individuals are more sensitive to possible health risks as a result of social linkages, they may follow that increased concern with information seeking, and eventually risk protective behaviors.
In recent years, a number of national and international research projects have documented the increased incidence of breast cancer among teachers (1.5 times higher). In response, Cornell University and the National Education Association conducted a regional study of New York State teachers and educational support professionals to investigate their knowledge and perceptions of breast cancer risk factors (N=1114).
The study found mixed support for the hypothesis that family status, social networks and social integration influence risk perceptions and information-seeking behaviors. Most prominently, however, is that communication about health issues among members within a social network, community participation and general participation activities are significant predictors of increased risk perception, health concerns in the school and the community, and health information-seeking behaviors. These findings suggest that there is a need to build into breast cancer risk communication efforts in understanding an individual?s perceptions and information-seeking behaviors.

title: Individual differences in irony production and use
abstract: What factors affect the way an individual processes and uses irony? The present research investigates whether cognitive flexibility, conversational indirectness, and personality traits may account for the differences in an individual?s use of irony. The results of this study suggest that cognitive flexibility and personality traits predict irony use. An individual who is cognitively flexible is more likely to use irony and better at interpreting it because he/she can process the multiple interpretations presented by ironic language. Agreeable and conscientious people are less likely to use irony because of their innate personality traits and the harsh, critical nature of ironic language. These results suggest that agreeableness and conscientiousness are personality traits that determine which type of sarcasm an individual may use in daily interactions, while cognitive flexibility seems important to situational forms of irony. These individual differences support a view of irony as cognitively complex and interpersonally critical.

title: The Crying Game: An examination of how stereotypes affect witness credibility
abstract: Stereotypes are constantly utilized to draw inferences and evaluate information, regardless of whether or not individuals employing them are cognizant of this fact. However, when jurors who are responsible for evaluating the truthfulness and credibility of witness testimony rely on stereotypes regarding the emotional responses of men and women to judge witness testimony, the conclusions they draw may be tainted. In this study, six experimental conditions were constructed to ascertain whether witness testimony would produce different effects if male and female witnesses delivered testimony while showing emotions stereotypical of their genders or emotions unexpected of their genders. While testifying that they were the victims of an armed robbery, male and female witnesses showed fear, anger, or no emotion. It was found that when male witnesses displayed the stereotypical emotion for their gender, anger, the participants rated the guilt of the defendants significantly higher than when female witnesses displayed the same emotion. Conversely, when female witnesses displayed the emotion stereotypical for their gender, fear, the participants rated the guilt of defendants significantly higher than when men displayed fear. It was also found that female displays of anger and fear produced a much greater difference in guilt rating for defendants than male changes in emotion. Additionally, over all experimental conditions, witnesses were believed to be telling the truth most when they showed fear and least when they showed anger.

title: The Geographic Basis of Food Insecurity in Sub-Saharan Africa
abstract: One out of every three people lacks access to sufficient nourishment in sub-Saharan Africa, the region with the greatest food insecurity in the world today. Low agricultural productivity and expansionary demographic trends will necessitate greater reliance on imports if the food needs of the region are to be met in the future. However, sub-Saharan Africa is distant from major food export markets, and many of its countries are landlocked. In my research, I quantify the influence of the region?s transport-prohibitive

characteristics on food security. By constructing regression models from agricultural trade data, I demonstrate that geographically isolated countries face substantially higher grain import prices, and these higher prices can raise the prevalence of hunger. I find that 300 kilometers between the port of disembarkation and the major population agglomeration in the importing country explains a one percentage point increase in the undernourished population. This result highlights the needs for infrastructure investment and low trade barriers to minimize the cost of remoteness and promote the eradication of hunger in the region.

title: Gender Perception Differences for Relationships Portrayed on Television
abstract: Television and other media influence expectations and perceptions of love and marriage. In this experiment, various gender behaviors of sex and relationships were shown in the context of romantic relationships on television. Participants? interest, character approval, and perceived realism were compared between expected and not-expected gender behavior for white and black television characters. The results indicate that, in general, characters are seen as less real, and receive lower approval ratings, when expected gender behavior is violated. However, male participants may have different perceptions regarding television characters than female participants due to the genre through which romantic relationships are shown on television. These findings contribute to previous research that preconceived gender expectations affect how we perceive and define gender roles in both television shows and reality.

title: Keeping Stolen Land
abstract: This thesis explores the common roots of several contemporary social movements in Durban, South Africa. My point of departure is a series of community meetings in May, June, and July 2006, during which geographically separated Black and Indian community organizations expressed remarkably similar grievances against the municipality and government, all rooted, I argue, in the colonial dispossession and alienation of Africans, and later in the enforced marginalization of Indian communities. Largely, these dispossessions occurred in the 19th century and early in the 20th century ? decades before the policy Apartheid begin in 1948. It is the continued relationship of exclusion and repression in relation to land and space in Natal, I argue, that accounts for the common struggles of these movements. I shall cite Antonio Gramsci extensively in order to argue that his conceptions of ?consent? and ?coercion? explain the perpetual success of policies designed to preserve colonial and Apartheid dispossession. Moreover, several labor struggles will be considered in order to illustrate the degree to which the majority's consent has been secured, and to offer evidence that Gramsci?s theories are powerful assistance to us. Mahmood Mamdani?s identification of "subject" and "citizen" will factor, as the transition from Apartheid to ANC rule has essentially cemented the status of landless South African subjects. His lengthy iteration of indirect rule in Apartheid South Africa will become crucial to understanding how the transition was ineffectual for many.
In addition, by surveying documents relating to the management and control of these populations, I argue that KwaZulu-Natal?s managers, through several succeeding governing regimes, have implemented policies of great similarity to achieve the same effect ? keeping the power of land and space of Natal in the hands of Europeans. In response, a range of land, labour and housing community organizations have protested their government and voiced demands that show a continued resistance to policies of exclusion from and access to valuable land and space in the province. From their concerns and mobilizations, I will finally attempt to

construct an understanding of what has, and has not, changed in South Africa.

title: The Effects of Animal Narratives on Learning
abstract: Previous studies show that the degree to which an individual is transported into a narrative influences the way the story affects their attitudes and beliefs. This study looks in particular at how individuals learn about animals through animal narratives. We manipulated visualization, anthropomorphism, story type (fiction/non-fiction), and factuality to determine how these factors influence both transportation and learning. Our findings determined that there was no significant influence of visualization on the degree of transportation experienced by participants (p>.05). Results found that anthropomorphic stories were less transportive than non-anthropomorphic stories. Data also concluded that participants more highly transported answer more questions correctly, implying a higher rate of learning.

title: Rethinking the Quarterlife Crisis: Expected Geographic Mobility among Young Adults in Flanders, Belgium and Upstate New York
abstract: In the United States, the concept of quarterlife crisis is an increasingly recognized social phenomenon. However, much about this dynamic period in the life course, and its impact on individuals remains undocumented. For example, how does the quarterlife transition inform individuals? expectations about their future geographic mobility? It is important to ascertain whether the quarterlife experience is salient across national boundaries, and whether it has a similar impact on the expectations of young adults in various cultural contexts. Cross-cultural findings could yield valuable data for policy-makers or employers aiming to attract or retain young adults within a specific region. To explore the universality of quarterlife transition, I compare the expected geographic mobility of college students preparing to graduate in two different regions: Flanders, Belgium, which is characterized by retention of young adults, and upstate New York, which has seen immense out-migration of young adults in recent decades. Interviews conducted with graduating college students in both locales provide a foundation of qualitative data. To understand the personal allegories and stories that individuals shared with me, I apply an analytical thematic framework rooted in sociological life-course theory. Life-Span Development, Agency, Time and Place, Timing, Linked Lives comprise the five paradigmatic principles used to create a comparison of young adults in Flanders and upstate New York. This rubric sheds lights on similarities as well as several important differences in how individuals experience the quarterlife transition in different regions and which factors inform their expectations about future geographic mobility.

title: The Diffusion of Prediabetes Information through Healthcare Facilities
abstract: Prediabetes is defined as a condition that develops when a patient's blood sugar level falls between the normoglycemic and diabetic range. Prior research suggests that the loss of ten percent of body mass in a pre-diabetic patient may eliminate or prolong the onset of diabetes. However, a recent study conducted

shows that physicians do not know how to diagnose prediabetes. This current investigation explores the spread of prediabetes information through the perspective of the diffusion of innovation theory. Methods. A secondary analysis of the physician assessment on diabetes knowledge established the problem. A follow-up survey was distributed to physicians to explore the effectiveness of communication sources. Results. The presence of barriers to information is associated with less time researching a topic. The most frequently used medium is internet, and the more sources that are used when researching the topic is correlated to a higher perception of knowledge on prediabetes. A physician will attend an information session run by a physician that he admires regardless of the topic. Conclusion. A secondary analysis established that physicians are not correctly diagnosing prediabetes. The follow-up survey suggests confirmation of three hypotheses, hypotheses: (1) physicians are less likely to spend time researching a topic when a barrier is present, even if they perceive ease in accessing medical information, (2) physicians who use more information sources perceive that they are more informed, and that the internet is the most effective medium when researching medical information, and (3) physicians are more likely to attend an information session run by a physician they admire, regardless of the topic.

title: Eating Restraint and Food Power as Predictors for Consumption and Freshman Weight Gain
abstract: The objective of this study is to examine the relationship between dietary restraint, consumption, and freshman weight gain. It was hypothesized that restrained eaters are more responsive to environmental cues, will eat more when served more food, and will gain weight during their first semester at Cornell. Fifty freshmen attended a session at the Human Metabolic Unit and answered two questionnaires: The Eating Habits Questionnaire and Power Food Scale, and body weight was measured. They were served an all-you-can-eat lunch of pasta, marinara sauce, salad, dressing, and soup. Food intake was measured and recorded. After two weeks, the subjects attended a restaurant-style lunch and were served 1.5 times what they ate at lunch one. When subjects finished eating, they were offered an all-you-can-eat dessert of chocolate cake and ice cream. Again food intake was measured and recorded. Change in food intake across lunches was determined. At the end of the semester, subjects were weighed again to determine body weight change.
The evidence all in, the conclusion is inescapable: restrained eaters are more responsive to environmental cues and have higher food power scores. In this study, eating restraint was an accurate predictor of food intake and the more restrained eaters ate significantly more when served more food and when served dessert compared to less restrained eaters. A significant freshman weight gain of approximately two pounds was also determined, but the association between restraint and weight gain was not significant. This study should be tweaked and replicated so that the relationship between dietary restraint, consumption, and freshman weight gain can be understood. With the appropriate data available, policy changes can be made to implement changes on college campuses that will help combat disordered eating patterns that are characteristic of restrained eaters.

title: Strain and Gender Differences in Expression of BK Potassium Channel Subunits in Mouse Adrenal Gland
abstract: Sexual dimorphisms in adrenal function and distinct behavioral patterns of aggression and “emotionality” in SJL and C57/BL6 mouse strains led to an intriguing question: are there strain- and/or

gender-specific differences in the adrenal gland at the level of ion channels? In this study, we focused on the adrenal medulla, which is a critical component of the neuroendocrine system and responsible for modulating reactions to stress and regulation of various body processes including digestion, the immune system, mood, and energy usage. Secretion of epinephrine (EPI) from chromaffin cells of the adrenal medulla is tightly controlled by the electrophysiologial response generated from neural inputs. Several studies suggest that the intrinsic excitability of these cells is modulated by the number and kenetic properties of large-conductance calcium(2+)-activated potassium ion channels (BK channels). Therefore, we focused on BK channels to study strain- and gender-specific differences in the adrenal gland at the level of ion channels. Stress- and sex-steroids have been shown to regulate alternative splicing of the pore-forming subunit of BK channels (Slo-?) in several experimental contexts, and associated ?-subunits confer on BK channels distinct sensitivities to acute effects of stress- and sex-steroids. Using a real-time PCR technique, we examined mRNA levels for total Slo, STREX (a stress-regulated splice-variant of Slo), ?2, and ?4 in two mouse strains, SJL and C57/BL6. The experimental groups were: SJL males, SJL females, and C57/BL6 males. SJL males expressed significantly higher levels of mRNA for total Slo, ?2, and ?4 than SJL females and C57/BL6 males. STREX levels were not significantly different between the groups, probably due to a small sample size, but on average, SJL males had higher levels of expression than the other two groups. These results suggest that SJL females and C57/BL6 males are relatively similar in their BK channel expression in the adrenals, while SJL males show distinct expression patterns. From this study, we now have grounds for hypothesizing functional relationships between behavior and adrenal function.

title: In Their Own Voices: A Conversation with Howard W. Riley: Early Agricultural Engineering at Cornell University
abstract: In August of 1963, Dr. Gould Colman, University Archivist Emeritus, interviewed Professor Howard W. Riley, who was the head of the Department of Agricultural Engineering from 1907-1945. In these interviews, Professor Riley candidly records his accomplishments and mistakes, describes his limited access to educational resources that now seem primitive, and repeats his commitment to the overriding goal of teaching and research in the College at the time, and helping New York's rural people improve life's quality in farm and home life.

title: FUNCTIONAL CATEGORIES IN EARLY LANGUAGE ACQUISITION: THE CASE OF DETERMINERS
abstract: This dissertation explores the status of Functional Categories (FCs) - the grammatical categories that are realized in language by a closed-class set of Function Words (FWs; e.g., "the", "and") and bound morphemes (e.g., -ed, -s) - in children?s early representation and processing of language.
Since FCs play a fundamental role in establishing the structural skeleton of sentences, a crucial question is when and how do children incorporate the functional lexicon into their representation and processing of language. On one view, children initially focus on content words such as nouns and verbs and on the basis of these infer meaning and reference. An opposing view is that FCs guide and facilitate the child?s acquisition of language from the earliest developmental stages. Specifically, by serving as primary cues for word learning, word categorization and sentence computation purposes.

This research program investigated whether children may consult the grammatical role of FWs in sentences - in particular, Determiners - already at 1-to-2 years of age. In three experiments, 12, 18, and 24-month-old infants were tested on a preferential-looking task which contrasted grammatical sentences (e.g., ?can you see the ball??), versus three ungrammatical conditions in which the determiner ?the? was either dropped, replaced by a nonsense word, or replaced by an alternate English FW (?and?).
Both the 18- and 24-month-olds oriented faster and more accurately to target following grammatical sentences in comparison to the ungrammatical conditions. A group of 12-month-olds tested on the exact same task failed to show such differences. However, another group of 12-month-old infants who were first familiarized with the test nouns and their respective images, oriented faster to target following grammatical sentences in contrast to the two ungrammatical substitution conditions (and/el).
These findings demonstrate that already around the 1-year marker - although FWs are typically omitted from children?s productive speech (in English) - infants incorporate syntactic information regarding FWs in sentence processing. This early grammatical sensitivity enables the syntactic categorization of words and facilitates reference determination. This suggests that both lexical (content) word categories as well as functional word categories are developing in tandem during these critical periods in language acquisition.

title: Homogeneous genetic structuring and microsatellite allele diversities across White-ruffed Manakin (Corapipo altera) populations in a highly fragmented Costa Rica landscape
abstract: We explored the effects of recent forest fragmentation on fine-scale patterns of population structuring and genetic diversity in populations of White-ruffed Manakins (Corapipo altera) inhabiting premontane forest patches of varying size in southwestern Costa Rica. Habitat fragmentation is a major conservation concern for avian populations worldwide, but studies on the genetic effects of fragmentation on Neotropical birds are limited. We sampled 159 manakins from nine forest fragments of varying size and isolation within an 18 kilometer radius, and genotyped these birds at 13 microsatellite loci. Bayesian clustering methods revealed that birds from all fragments comprised a single genetic population, and F-statistics showed only modest levels of differentiation between forest patches. We calculated allelic diversity indices for each fragment but found no correlation between genetic diversity and fragment size. These results suggest two possibilities: first, these manakins may retain substantial connectivity via inter-fragment dispersal despite habitat fragmentation, or if dispersal is currently limited, the short period of a half-century since fragmentation may not have been sufficient to impose genetic structuring or to erode allelic diversity.

title: MHC Class I Sequence Polymorphism in Horses and Donkeys
abstract: This study investigated the number of Major Histocompatibility Complex (MHC) class I genes in donkeys, their polymorphism, and their phylogenetic relationship to MHC class I genes of the horse. It has been found through bioinformatic analysis of MHC class I sequences of horses of different haplotypes that classical MHC class I alleles commonly fall within four loci, with additional individual genes that do not fit within any of the four loci. Conserved regions of horse and donkey MHC class I sequences were used to design PCR primers that amplified donkey class I genes. RT-PCR reactions were carried out on donkey lymphocyte cDNA. The MEGA 3 program was used to cluster related sequences and to assign them to individual loci. Donkey sequences followed a similar pattern to that of the horse, having a few loci that contain many of the

alleles and additional MHC class I loci that may be unique to one or only a few MHC haplotypes. The donkey alleles fell into either previously established horse loci or loci unique to donkeys. Loci shared between horses and donkeys are probably older loci, having evolved before the split of hoses and donkeys, while loci detected in only one species may be younger. Comparing the allelic variation between horses and donkeys will lead to a better understanding of the evolution of the highly variant MHC region.

title: Riley-Robb Hall at Cornell University: Celebrating It's Opening abstract: In the fall of 1953, 46 years after the Department of Biological and Environmental Engineering at Cornell was founded (in 1907) as Division of Rural Engineering and Architecture, ground was broken for what would become its own home, Riley-Robb Hall, named after its founding fathers, Howard W. Riley and Byron B. Robb. The building was dedicated on October 6, 1954, and in 1956 the Agricultural Engineering Department, as it was then named, occupied its new 2 ¼ acre facility for teaching, research and extension. By Fall Semester 1957, 38 professorial and non-professorial staff, 6 graduate students and 12 office professionals were on the roster, as shown in the new directory of September 25, 1957 in the Appendix. Pictures of many of these individuals can be seen in the photographs included in this album. The appendix contains a listing of this 1957 directory.

title: Bioassay of Vitamin A2 in the Retinal Tissue of the zebrafish, Danio rerio, Using Microspectrophotometry and 2D-Imaging
abstract: Zebrafish have been shown to utilize the vitamin A1 chromophore in synthesizing their visual pigments. Recent evidence suggests that they may also be able to utilize vitamin A2 under both natural conditions and after treatment with thyroxine. To test for the presence of vitamin A2 in the retinae of zebrafish and map its location, I combined microspectrophotometric (MSP) analysis with 2D-imaging. MSP measures the absorbance spectra of visual pigments within single photoreceptors, while 2D-imaging uses differential bleaching to attempt differentiation of those regions rich in A1 pigment from those containing A2. Previous MSP has found the occasional A2 cell in some fish, but failed to demonstrate a specific area or island utilizing the A2 chromophore in zebrafish, possibly due to sampling problems of the MSP technique. Unfortunately, the 2D-imaging failed to show enough contrast between bleached and unbleached retinal regions to determine if, in fact, bleaching occurred at all.
In an attempt to enrich the retina in vitamin A2, thyroxine treated eyecup cultures were used. In this case the hope was to stimulate A2 synthesis in cultured eyecup preparations. MSP was used to monitor changes in vitamin A2-based pigment. There was a failure to observe A2 synthesis in culture. While the most likely culture conditions were tried first, it is believed that these were NOT conducive to zebrafish retinal culture. This study has demonstrated methodological challenges that need to be solved before the original question can be satisfactorily addressed.

title: The Mammalian Oviductal Sperm Reservoir: Identification of Receptors for Bull Sperm on the Oviductal

Epithelium
abstract: In eutherian mammals, a storage reservoir is formed when sperm become trapped in the initial segment of the oviduct by binding to the epithelium lining its wall. In bull sperm, seminal vesicle secretory proteins in the bovine seminal plasma (BSP) protein family, namely PDC-109 (BSP A1/A2), BSP-A3, and BSP-30-kDa, coat the sperm head and enable sperm to bind to the oviductal epithelium. This study was undertaken to identify at least one receptor for BSP-30-kDa on the oviductal epithelium. Proteins extracted from apical plasma membranes of the oviductal epithelium were added to a column of BSP-30-kDa bound to anti-BSP-30-kDa covalently conjugated to Protein-A agarose beads. Unbound proteins were washed from the beads and proteins that bound to the column were eluted by adding EGTA, a calcium chelator, because sperm binding to the oviductal epithelium is dependent on calcium. The eluates were resolved on SDS PAGE gels, and silver staining detected two prominent bands of approximately 37 and 34 kDa. Tandem mass spectrometry identified the protein constituents of the bands as annexins (ANXA) 1, 2, and 4. Anti-annexin antibodies also labeled the cilia and apical surfaces of the epithelium in sections of bovine oviduct. Annexins belong to a multigene family of calcium-dependent, phospholipid binding proteins. Annexins are important in several biological processes such as cell adhesion, ion channel modulation, signal transduction, and regulation of membrane structure. It was concluded that annexins are primary candidates for the sperm receptors on bovine oviductal epithelium.

title: MRE11 is Unlikely to be an Essential Component of the Saccharomyces cerevisiae Mismatch Repair Pathway
abstract: hMRE11 has recently been implicated as a primary factor in human mismatch repair (MMR), a process which acts to improve DNA replication fidelity. Mutations in hMRE11 have been identified in human nonpolyposis colorectal cancer (HNPCC) related tumors and in vivo mutator assays suggest that knockdown of this gene causes frameshift mutations. I report that the deletion of MRE11 from the Saccharomyces cerevisiae genome increases the mutation rate but does not significantly enhance the rate of frameshift mutations as seen in other yeast MMR mutants. In addition, unlike in mammalian systems, I was unable to observe yeast two-hybrid interaction between MRE11 and MLH1. This combined evidence suggests that MRE11 is unlikely to be a major player in yeast MMR.

title: The effects of aedeskinin III and analogues on transepithelial electrolyte and fluid secretion in Malpighian tubules of the yellow fever mosquito
abstract: The effects of synthetic aedeskinin III on transepithelial electrolyte and fluid secretion were studied in isolated Malpighian tubules of the yellow fever mosquito, Aedes aegypti. Isolated Malpighian tubules were prepared for measurements of fluid secretion rates by the method of Ramsay. After measuring a control rate of fluid secretion, aedeskinin III was added to the peritubular Ringer solution. Rates of transepithelial fluid secretion significantly increased in a dose-dependent manner at aedeskinin concentrations ranging from 10-5 to 10-9M. Maximal stimulatory effects were observed at 1 ?M aedeskinin III, which increased the fluid secretion rate from 0.667 to 1.451 nl/min. EC50 for aedeskinin III was calculated as 1.028x10-7M. In the presence of 1 ?M aedeskinin III, the Na+ concentration in secreted fluid significantly decreased from 130.5 to 88.2 mM and the Cl- concentration in secreted fluid significantly decreased from 208.6 to 173.5 mM. The

increase in the K+ concentration from 82.1 mM to 90.3 mM was not significant. The product of the fluid secretion rate and electrolyte secretion yields the electrolyte secretion rate. Accordingly, the transepithelial secretion rate for Na+ increased from 96.3 pmols/min to 127.6 pmols/min, the K+ secretion rate increased from 61.6 pmols/min to 141.2 pmols/min, and the Cl- secretion rate increased from 153.9 to 257.5 pmols/min. However, only the effects on K+ and Cl- secretion were statistically significant. Synthetic aedeskinin-receptor agonists 1577 and 1460II also stimulated fluid secretion at 1 ?M concentrations, increasing fluid secretion rate from 0.716 to 1.224 nl/min and from 0.889 to 1.615 nl/min, respectively. The in vitro longevity of isolated Malpighian tubules was also assessed. Isolated tubules cultured in Ringer solution and Grace?s insect medium (pH 6.1) did not survive the process and did not secrete fluid one day after isolation. However, when kept in Grace?s insect medium at pH 7.1, the tubules still secreted one day later. These studies confirm that aedeskinin III has diuretic effects in Aedes Malpighian tubules. Rates of transepithelial secretion of NaCl and KCl increased, suggesting that the mechanism of action of aedeskinin III is similar to that of leucokinin. My study documents further and for the first time that synthetic analogs of aedeskinin containing ?-amino acids retain diuretic potency.

title: Hawaii Residents' Attitudes Towards the Management of an Invasive Frog Species (Eleutherodactylus coqui)
abstract: The coqui frog Eleutherodactylus coqui was unintentionally introduced to Hawaii in the late 1980?s. Since its introduction, the frog has been discovered in four islands: Oahu, Maui, Kauai, and Island of Hawaii. Much research has been done regarding the management of the coqui frog, including evaluation of control options involving the use citric acid, hydrated lime and chytrid fungus; however, little research has been done to address the societal impacts of the coqui frogs or the attitudes of Hawaii residents and their support for various management options. A self-administered mail questionnaire was used to evaluate Hawaii residents? perceptions toward the frog and its management. (32.4% response rate, n=653). A majority (72.4%) of respondents do not enjoy the presence of the coqui frog and consider it a nuisance while others (20.1%) simply do not care about it. Residents of the Island of Hawaii and those who had been born in Hawaii State are more likely to consider the frog a nuisance and to favor the different management options compared to residents of other islands and those not born in Hawaii. Although most respondents considered it very important for the government to manage the coqui frog, support for management decreased when respondents were asked about their support for specific management methods, most of which are lethal to the frog. Using the New Ecological Paradigm (NEP) Scale, it was revealed that most respondents tended to have a proenvironmental orientation. Respondents? knowledge and proenvironmental orientation were associated with the degree of management that they would support. However, a proenvironmental orientation was not always associated with support for the management of the coqui frog. Managers may be able to use communication strategies to increase public understanding about the ecological impacts of the coqui and the implications of specific management options, appealing to Hawaii residents? proenvironmental orientation.

title: Why does parental effort of the common tern (Sterna hirundo) decrease after a late-season flooding event? A multi-hypothesis approach
abstract: The production of two clutches within the same breeding season is uncommon amongst many

shorebirds species, and even more rare is the act of double-brooding. In late June of 2006, heavy rains flooded over 120 common tern (Sterna hirundo) nests, causing a re-nesting effort of over 140 pairs, and perhaps one case of double-brooding. To evaluate the level of parental effort after a late-season flooding event, I weighed and then compared the eggs of the second clutches to corresponding egg data from the first clutches of 1983 and 1984 from the same colony on Oneida Lake, NY. The mean egg weights from the second clutch of 2006 all weighed significantly less than the corresponding mean egg weights of the first clutches of 1983 and 1984. In both first and second clutches, there was a linear decrease in egg weight with laying order. Three hypotheses have been postulated to explain the intraclutch variation of egg weights, the "brood-survival", "brood-reduction", and "insurance" hypotheses attempt. Given the circumstances of 2006, the brood-reduction hypothesis fits best at explaining the intraclutch variation in egg weights.
The observed decline in parental effort late in the season can be explained by the ?timing? hypothesis, which in the case of this study included a decreased food supply and reduced breeding synchrony later in the season. Certain aspects of the life history of common terns such as molt, which overlapped with the production of the second clutch, as well as the allocation of energy between parents in a bi-parental care system, also decreased the success of many second clutches. Many adults associated with second clutch nests abandoned their eggs and/or chicks in order to enhance the probability of their own survival.

title: Phenotypic characterization of dimple, an embryonic lethal mutation that affects epithelial to mesenchymal transition during mouse gastrulation
abstract: During mouse gastrulation, an epithelial to mesenchymal transition (EMT) takes place at the primitive streak, in which epithelial cells ingress and migrate laterally to form the mesoderm. This process requires disassembly of adherent and tight junction complexes. From a mutagenesis screen, a mouse mutant dimple with defects associated with EMT was isolated and the mutation most likely affects the splicing of MAGI-1 transcript. dimple mutants display abnormal cell accumulation at the mesodermal wings and embryonic development is arrested between embryonic day 7.5 and 8.5. In my thesis project, I show that MAGI-1 is localized in the apical face of epithelial cells where ZO-1 and E-cadherin are also present. In addition, the expression pattern of MAGI-1 at the primitive streak implies the dynamics of tight junction disassembly during EMT. In dimple mutants, I find there is a MAGI-1 isoform that is present in the wild type but most likely missing in dimple. More importantly, I show that E-cadherin in epithelial and mesenchymal cells of dimple mutants is prematurely down regulated. Based on my results, I propose that in dimple mutants the absence of MAGI-1 from embryonic epithelia, although does not seem to affect the integrity of tight junctions, somehow influences the localization and transcriptional regulation of E-cadherin. This down-regulation of E-cadherin at the primitive streak might cause a premature EMT and disrupt the pace of cell delamination during gastrulation, generating the excess of mesenchymal cells and absence of delaminating cells at the primitive streak that we observed in dimple mutants.

title: Specificity of herbivore-induced secondary metabolite responses in tall goldenrod, Solidago altissima
abstract: Plants respond to herbivore damage with a bewildering array of metabolic responses. To what degree such responses are specific to particular herbivore species and how plants respond to multiple attackers are questions of extensive scientific debate because their answers are fundamental to the understanding of the

ecological consequences of plant induced responses to herbivory. In a field experiment, I investigate the nature of secondary metabolite and defensive protein production in Solidago altissima when elicited by two different herbivore species, the larvae of the galling fly Eurosta solidaginis and the chrysomelid beetle Trirhabda virgata, individually or at the same time. The chemical analysis of leaf tissue reveals differential responses in both trypsin proteinase inhibitor production and volatile organic compound emission when goldenrod plants are damaged by either herbivore individually or the two in combination. Our findings suggest damage-specific elicitation and signal transduction for each herbivore individually and for when both attack simultaneously.

title: Structure of BAR and PX domains of Sorting Nexin 9 reveals cooperativity in membrane binding
abstract: Sorting nexin 9 (SNX9) belongs to a larger family of BAR-domain containing proteins. It is characterized by an N-terminal Src homology 3 (SH3) domain, a phox homology (PX) domain, and a Bin/Amphiphysin/Rvs-homology (BAR) domain. Together with clathrin and dynamin, it functions mainly in the endocytic pathway to sort proteins. SNX9 has also been shown to regulate receptor-mediated endocytosis of epidermal growth factor receptor (EGFR), by its interaction with Activated Cdc42-associated kinase-2 (ACK2), thus implicating a role for SNX9 in signal transduction.
Although the main cellular functions of SNX9 have been brought to light, little is known about the molecular mechanism by which this multi-domain protein participates in endocytosis and signaling. It is also unclear if and how the protein is regulated. In order to understand the interactions between the various domains of SNX9, we have crystallized and solved the structure of a shorter construct of SNX9 (here after called SNX9PX-BAR), which consists of only the PX and BAR domains. By analyzing this multi-domain structure and by conducting lipid- and vesicle-binding assays, we are able to gain a better understanding of how the two domains interact to influence the membrane binding ability of SNX9.
Our analysis of the structure of SNX9PX-BAR shows a dimeric BAR domain that is moderately curved. The BAR domain forms stable dimers via mainly hydrophobic interactions on the membrane surface. Membrane binding is most likely driven by electrostatic interactions between the PX-BAR domain and the negatively-charged plasma membrane. In addition, the PX domain of SNX9 shows high and specific binding affinity to PI(3)P, which is in high concentrations in early endosomes. Therefore, we propose that SNX9 might be localized to both the plasma membrane and the early endosomes to participate in endocytosis and sorting of vesicles.

title: Changes in fin whale (Balaenoptera physalus) song over a forty-four year period in New England waters
abstract: Although much marine mammal research has been conducted on whales in the waters surrounding Cape Cod, Massachusetts, little work has been done on the supposed resident fin whale (Balaenoptera physalus) population that resides in this area. Fin whales have three different sounds in their vocal repertoire but a relatively simple song that is composed of long trains of high intensity 20-Hz pulses. Performed only by males, the song may be a reproductive display with song characteristics evolutionarily fixed within populations. In this study, fin whale vocalizations recorded in the area of Cape Cod Bay during the years 1961, 1978, 2001, and 2005 were characterized and compared within years to detect possible divergence in

the male song. Reliable comparisons with the earlier data proved difficult because of small sample sizes under the chosen song parameters. However, measurements of inter-pulse interval and song length did vary significantly between the short time span of 2001 to 2005. Mean inter-pulse intervals were shorter in 2001, and song duration was longer within the 2005 recordings. Negative correlations between the center frequency and the song duration, as well as the center frequency and inter-pulse interval were also found. Although we rejected the null hypothesis that song notes and features are fixed and do not change over time, we did discover valuable information regarding the relationships between different features of fin whale song. Based on comparison of the temporal and individual variation observed in our data with those collected on a population in Bermuda, it is unclear whether vocal characteristics are distinct and could be an identifying feature of separate breeding populations.

title: Effects of SOPC on the Phase Behaviors of the DSPC/DOPC/Cholesterol Biomembrane Model System
abstract: The phase diagram of the DSPC/DOPC/cholesterol biomembrane model system was recently determined by studies in our laboratory. However, the component DOPC does not occur in animal cell plasma membranes, but was chosen for convenience in solving the phase diagram. In my study, DOPC was replaced stepwise by the naturally-occurring SOPC to determine its effect on the high cholesterol boundary of the L?+Lo two-phase region. Giant unilamellar vesicles with the chosen compositions, probed with the fluorescent dye C12:0-DiI, were made by electroswelling and their phase behaviors were examined by fluorescence microscopy. From 0 to 45% replacement of DOPC by SOPC, the middle part of the boundary shifts only a small amount, from cholesterol mole fraction 0.38 down to mole fraction 0.30 ? 0.35. The L? side of the boundary remains essentially unchanged. Above 50% replacement, photo-induced artifacts obscure the real phase behavior at the middle part of the boundary, but might represent the actual boundary termination. Above 70% replacement of DOPC by SOPC, no phase-separation was observed for the L? side of the boundary. The size and shape of the L?+Lo two-phase region can be related to the structures of the lipids.

title: Relaxation of microhabitat restriction through ontogeny of Itea virginica in cypress-tupelo swamps
abstract: Nearly all understory plant species in semi-permanently flooded cypress-tupelo swamp forests grow on microsites located above the water level, as opposed to growing on the flooded forest floor. Our field study indicates that one such species, Itea virginica (Saxifragaceae), has a strong association with elevated microsites that changes with life stage: adults are found significantly more often on the forest floor than seedlings, although not as frequently as expected for the amount of forest floor vs. elevated microsites present. High water level may inhibit seedling establishment, but not adult growth, thus suggesting a potential ontogenetic expansion of flooding tolerance. We conducted greenhouse flooding experiments on seedlings and adults of various sizes with three treatments: high flood (a percentage of aboveground biomass submerged), waterlogged (only root systems submerged), and control (no flooding). The effect of initial height above water and treatment on relative growth rate was significant for the seedlings: RGR decreased with increasing flood level; however, there was no significant effect for adults. Seedlings were more negatively affected by flooding than adults due primarily to their small size rather than any differences in ability to produce flood responses (i.e., enlarged lenticels or adventitious roots). Additionally, we conducted seed experiments investigating the

effects of different substrates and durations of flooding on germination success; there were no significant effects of either factor on seed germination. This study increases our understanding of regeneration biology and can be valuable in planning restoration activities in cypress-tupelo swamps.

title: When getting a meal may cost your life: Exploring the incongruous distribution between the green crab Carcinus maenas and its prey
abstract: The green crab Carcinus maenas invaded the Gulf of Maine over a hundred years ago and has become a well-established member of intertidal communities. We surveyed the vertical distribution of Carcinus, other crabs, and their potential prey from the intertidal into the shallow subtidal. Carcinus was most abundant in the intertidal and decreased in the subtidal. In contrast, a preferred prey of Carcinus, the mussel Mytilus edulis, had highest densities in the shallow subtidal. Why isn?t Carcinus most abundant where prey densities are highest? A previous experiment revealed a higher mortality rate for Carcinus tethered in the subtidal than in the intertidal. In the subtidal there are higher abundances of the American lobster Homarus americanus and Jonah crab Cancer borealis. We performed a laboratory experiment to investigate the effects of cohabitation with lobster and C. borealis on survival, shelter use, and behavior of Carcinus. Lobsters were the more effective predator on Carcinus, consuming 27% of the crabs during 24 hours. Only 5% of Carcinus were eaten by C. borealis and none by conspecifics used in control treatments. In the presence of lobsters, Carcinus showed significantly more climbing and deep burrowing behavior relative to controls. Our results suggest that the risk of predation by lobsters underlies the scarcity of Carcinus in subtidal communities.

title: Dynamics of Supralittoral Freshwater Rock Pools in the Gulf of Maine
abstract: Appledore Island, located six miles off the coast of Portsmouth, NH, has over 500 freshwater peripheral pools situated above the intertidal zone and range in size from semi permanent pools measuring 15 centimeters across to larger permanent pools up to about 10m diameter. Seventy eight pools were physically monitored once every four days from June to August 2006 and have provided us with a deeper understanding on dynamics of pond community organization and how organisms cope with rapid and major physical changes. Pools were monitored for temperature, conductivity, pH, dissolved oxygen, water color and clarity, and presence or absence of key macrofauna. The color and clarity of pools, which we used as a proxy for phytoplankton levels, varied throughout the summer and ranged between being always opaque to always clear, or cycling between these two states. Cycling of pools is important for the macrofauna because it indicates varying conditions that organisms must contend with. Clear pools had significantly lower dissolved oxygen levels, pH values and presumably, based on water clarity, lower phytoplankton stocks, while opaque pools had higher levels of both dissolved oxygen and pH and usually very high phytoplankton levels. Diel vertical migration by Daphnia. pulex was observed in these island pools which is interesting because of the lack of vertebrate predators. Significantly higher densities of D. pulex occurred in the top 10cm during the night than day. With the absence of significant predators, physical or genetic factors must explain the observed migration to the surface at night by D. pulex.

title: The role of aphid host preference in barley yellow dwarf virus epidemiology
abstract: Viral infection can cause changes to a plant?s morphology or chemical composition that may alter its desirability to the insect vector. In combination with viral persistence in the vector, prevalence of the disease, and the spatial distribution of infected plants, vector preference for virus-infected or uninfected individuals can strongly influence the rate of disease spread in plant communities (McElhany et al. 1995). Although it is known that the presence of a virus in the host plant can lead to a change in feeding behavior and an increase in fecundity (Fereres et al. 1990, Fereres et al. 1989, Montllor and Gildow 1986), there is little evidence that vectors prefer infected hosts over uninfected hosts. In this study, I examined host preference of the grass-feeding aphids Rhopalosiphum maidis, R. padi and Sitobion avenae when offered a variety of grasses infected or uninfected with the PAV species of barley yellow dwarf virus (BYDV). The eight grass species used in the preference tests are commonly found in New York State and are known hosts of BYDV. Preference tests were carried out in cages, where adult aphids were allowed to choose among grass seedlings. To determine whether infection altered preference, aphids were offered either uninfected grass communities or communities that contained a mixture of infected and uninfected grass seedlings. Results from these trials indicated strong species-specific preferences by aphids for particular grasses. Although there was some indication that infection could alter preference, I found no evidence that infection caused a significant shift in preference ranking among grasses.

title: The Functionality of Marek's Disease Virus Us3 Protein
abstract: Marek's disease (MD) is a lymphoproliferative disease of chickens caused by cell-associated Marek's disease virus (MDV). The Us3 protein kinase expressed by MDV has been shown to be involved in various stages of the viral life cycle. Deletion of the Us3 open reading frame resulted in an accumulation of primarily enveloped virions in the perinuclear space which led to a reduction in viral titers (Schumacher et al., 2005). It was also shown that the Us3 protein is involved in actin stress fiber breakdown. In this study we constructed a recombinant virus (Us3*220A) to determine the significance of the Us3 kinase activity. Disruption of the kinase activity was achieved by substituting a lysine in the active site of the protein with an alanine. Titers of the kinase-negative virus were reduced when compared to parental virus in a similar fashion as the previously described Us3 deletion mutant. We were able to show complete absence of direct phosphorylation of an MDV-specific phosphoprotein, pp38 by pUs3*220A. Surprisingly, expression of pUs3*220A mediated breakdown of the actin cytoskeleton 24h after transfection of chicken embryo fibroblasts in the same way wildtype pUs3* does. At 48h post transfection the actin cytoskeleton was fully restored in almost all transfected cells. Our results show that the Us3 and pp38 proteins comprise a kinase-substrate pair but that not all of Us3 functions are mediated by its kinase activity.

title: Regulation of Proto-Dbl through the Ubox Domain of CHIP
abstract: The Dbl protein is a product of a proto-oncogene that functions as a guanine nucleotide exchange factor for Rho-family GTPases. It is responsible for activating the GTPases by facilitating the dissociation of GDP thus allowing for the binding of GTP. Intracellular levels of Dbl are regulated by ubiquitin-mediated

proteolysis. CHIP is the E3 protein-ubiquitin ligase responsible for this ubiquitination. More specifically, the Ubox domain of CHIP is critical to this interaction. Oncogenic Dbl, which lacks its spectrin domain, cannot bind CHIP and therefore escapes degradation. This causes accumulation of the oncogene product in the cell, and leads to persistent activation of its downstream pathways.

title: Engineering a Synthetic Extra-Cellular Matrix for In Vitro Cartilage Tissue Production
abstract: In this study, growth factor binding found in natural extra-cellular matrix (ECM) was mimicked by a modified polymer scaffold that could attract either Insulin-Like Growth Factor-I (IGF-I), a growth factor known to stimulate ECM production by chondrocytes, and Transforming Growth Factor-B1 (TGF-B1), a growth factor known to induce chondrogenesis in mesenchymal stem cells.
Short growth factor-binding peptides were synthesized and covalently attached to an alginate polymer scaffold. Using self-assembled monolayer (SAM) chemistry, these modified alginate layers were characterized using Imaging Ellipsometry (IE). Affinity of each growth factor for its respective synthetic peptide was quantified via Surface Plasmon Resonance (SPR). The density of binding peptides bound to alginate was determined using Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy (ATR-FTIR). Computational diffusion modeling was used to design an ELISA-based diffusion experiment. Mesenchymal stem cells and chondrocytes were grown in chemically modified-alginate beads with and without added growth factor; modification increased ECM production in both kinds of cells. Thus, through this novel system of peptide-modified alginate scaffolds, growth factors were specifically but non-covalently retained by alginate, allowing for controlled release of growth factors.

title: Characterizing the foraging ecology of leatherback turtles (Dermochelys coriacea) using stable carbon and nitrogen isotopes of eggshells
abstract: Stable isotopes are useful tools for discerning information regarding the foraging ecology of far-ranging animals like sea turtles. Isotope signatures of prey items are integrated into the turtles? tissues in a characteristic manner, and in the case of nesting females, eggshell isotopic signatures can provide insight into the trophic status and foraging locations of the adult females. By sampling eggshells from nesting beaches, one can obtain a unique, wide-range perspective that might not be observed by sampling turtles directly within foraging areas. In the present study, leatherback turtle eggshells were collected from 21 different nests on the nesting beach in Jamursba Medi, Papua, Indonesia in the Western Pacific in July 2003. Habitat samples, including particulate organic matter, krill, gelatinous organisms, squid, and small fish were collected with dip nets and bongo tows in the Eastern Pacific, off the west coast of the United States. Eggshell ?13C values were similar for all eggshell samples (-13.2 ? 1.2 ?). However, there was a dichotomy in ?15N values, with 62%

of the eggshells in the 9.2?-10.8? range and 38% in the 12.5?-14.5? range. Comparing these values with the ?15N values of habitat samples analyzed in this study and others as well as with information on Pacific-wide nitrogen fixation/denitrification patterns, suggests that these two ?15N groupings represent animals foraging in the Western Pacific and Eastern Pacific, respectively. These data are consistent with satellite telemetry data and suggest that ?15N isotope analysis can be an effective, non-invasive method to gain knowledge about turtle foraging locations that may prove useful in conservation efforts.

title: Retronasal but not oral-cavity identifications of air-phase trigeminal stimuli
abstract: Single concentrations of six odorants (eugenol, heptyl alcohol, nonanal, 1-octanol, dl-menthol, valeric acid) were selected to be trigeminal stimuli, based upon previous studies done through anosmics (individuals that lack a functional olfactory system). The stimuli were presented in random order three time each in vapor-phase either retronasally or oral-cavity-only. They were identified on a digital computer by 20 subjects (ages 18 to 35, 9 females). Retronasal presentations were produced by inhaling via the mouth with a nose clip closing the nostrils, and then removing the nose clip and exhaling from the nose. Oral-cavity-only presentations were produced by inhalation via the mouth with a nose clip closing the nostrils, and exhalation from the mouth with the nose clip remaining in place. This study investigates if subjects could identify odorants when restricted to the oral-cavity-only using the same identifiers of the odorants when presented retronasally. RESULTS: Median percent retronasal correct identifications [correct identification terms are shown in brackets] were: eugenol, 100% [cloves or spice]; heptyl alcohol, 67% [cleaner]; nonanal, 58% [citrus or floral]; 1-octanol, 71% [citrus or cleaner]; dl-menthol, 100% [ointment or peppermint]; valeric acid, 67% [rancid or sweat]. Median percent correct oral-cavity-only identifications were all 0%, except for dl-menthol, for which percent correct oral-cavity-only median correct identification was 67%. A Friedman Non-Parametric ANOVA statistical analysis showed significant difference between odorants presented oral-cavity-only versus retronasal. Pairwise comparisons showed significant differences between odorants presented oral-cavity-only versus retronasal for all odorants except for dl-menthol. CONCLUSIONS: Many vapor-phase 'trigeminal' odorants can be identified only when access to the nasal cavity (retronasal) occurs, but substantial correct identification of vapor-phase dl-menthol also occurs when restricted to the oral cavity (oral-cavity-only). Odorants similar to dl-menthol may contribute to flavor from both the oral and nasal cavities.

title: Mapping and identification of suppressor mutations of sma-9, a gene required for patterning of the postembryonic mesodermal lineage in C. elegans
abstract: The Caenorhabditis elegans M lineage provides an excellent system for studying mesodermal development. During C. elegans postembryonic development, the mesodermally derived M cell undergoes four rounds of cell division before differentiating into body wall muscles, sex myoblasts, and macrophage-like cells called coelomocytes. The sex myoblasts undergo three more rounds of division and become further differentiated into eight uterine and eight vulval muscles. The first division of the M lineage is asymmetric, with a dorsal and a ventral cell being formed. The dorsal cell gives rise to the two coelomocytes, whereas the ventral cell gives rise to the two sex myoblasts. The sma-9 gene is required to regulate this dorsal-ventral asymmetry. In sma-9 mutants, the dorsal cell behaves like the ventral cell in the M lineage. As a result, sma-9 adult worms are missing the two dorsally derived coelomocytes and have two extra ventrally derived

sex myoblasts. In order to identify the molecular mechanisms on how SMA-9 functions to regulate this asymmetry, the Liu lab has previously isolated a number of mutations that suppress the M-lineage defect of sma-9 mutants. Two of these mutations, jj1 and jj3, have been previously mapped to genes in the TGF-B signaling pathway, sma-6 and sma-3. In this thesis, I describe my mapping of two other sma-9 suppressors, jj6 and jj4, as well as the sequencing of the jj6 mutation. jj6 is a mutation in the MH1 domain of the sma-2 gene, another gene in the TGF-B pathway, and jj4 maps to the left arm of Chromosome I, a region that does not contain any known TGF-B pathway genes.

title: Aerial competition for feathers by Tree Swallows (Tachycineta bicolor)
abstract: During the breeding season, Tree Swallows (Tachycineta bicolor) scavenge for feathers and use them to line their nests. Nest lining is known to be an important factor in Tree Swallow reproductive success, but competition for feathers has never been experimentally studied despite the fact that acrobatic aerial competitions for feathers are frequent and easily observable. To examine the proximate and ultimate causes of feather contests, I manipulated the nest-lining of breeding swallows and then observed individual behaviors throughout the breeding season. Both males and females gathered feathers, beginning with nest construction and continuing through chick rearing. It is clear that there are two distinct methods of feather gathering: feather ?collection,? an early-season behavior characterized by a lack of interaction with other birds, and feather ?contests,? conspicuous, aggressive interactions involving several birds. Contests over larger feathers were more intense than those over smaller feathers. Early-season contest winners tended to exhibit drop-catch displays with the feather, had well-feathered nests, and were ultimately reproductively successful; there is some evidence that these contest winners may be higher quality individuals. The number of feathers in the nest at the time of a contest was also an important determinant of behavior. A late-season individual with a well-feathered nest tended to participate less in contests and drop the feather more frequently. The associations and feedbacks among contest performance, individual quality, the number of feathers in the nest, and reproductive success indicate that feather contests involve complex behaviors that are highly variable among individuals and change in response to varying conditions.

title: Identification and Characterization of Lethal 6: a Chromosome 5 Embryonic Lethal Mutation in Mus musculus
abstract: Mus Musculus was randomly mutagenized using N-ethyl-N-nitrosourea (ENU). Mutations on Chromosome 5 were selected using the Rw inversion, a visibly marked, recessive, lethal inversion that covers almost fifty megabases (Mb). Multiple mutations were isolated from the subsequent three-generation mutagenesis screen, one of which was lethal 6. Using a combination of complementation tests and recombinational mapping, the lethal 6 region was narrowed down to less than 1.4 (Mb). There were thirty-eight candidate genes in this region of which 4 had already been mutated and yielded viable progeny. The coding regions of 80% of the remaining thirty-four genes have been ruled out from being lethal 6, although it is still possible that ENU affected the regulation of one of these genes. Mice homozygous for lethal 6 die around E8.0 and preliminary results from blastocyst outgrowth assays suggest that they are unable to implant.

title: Defining the Cytoplasmic and Nuclear Transport of CPV Capsids in Cells
abstract: Canine parvovirus (CPV) is a non-enveloped virus that replicates in the nucleus during infection. While it is known that it uses the cell?s microtubule network to traverse the cytoplasm, the route of nuclear entry is unclear. The nuclear pore complex was thought to be used by the virus due to the presence of nuclear localization sequences (NLS) in the VP1 protein. But recent studies in the minute virus of mice (MVM) have proposed that it induces breaks in the nuclear envelop before entering the nucleus via these breaks. In this study, Crandell Feline Kidney (CRFK) cells stably transfected with GFP-lamin A/C were micro-injected with CPV capsids whose distribution within the cells was then detected using fluorescent-labeled antibodies. The CPV capsids did not appear to induce breaks in the nuclear lamin structure of the cells that was observed for the MVM.

title: Small G-protein activation in articular chondrocytes by interleukin-6, interleukin-8, and osteogenic protein-1
abstract: The studies outlined in this honor?s thesis were designed to better understand the mechanisms at both the cellular and molecular levels associated with the onset of osteoarthritis. The horse was used as a model organism, and the experiments were performed on normal equine chondrocytes cultured in vitro. Interleukin-6 (IL-6) and interleukin-8 (IL-8) are known to have catabolic effects on the cartilage matrix while osteogenic protein-1 (OP-1) is a known anabolic factor. There is no complimentary information regarding the effects of these peptides on small G-protein (Cdc42, Rac, and Rho) activation in articular chondrocytes. The objectives of the present study were to determine the activation status of Cdc42, Rac, and Rho after treatment with IL-6, IL-8, or OP-1. The G-proteins play an important role in the maintenance of the actin cytoskeleton and chondrocyte phenotype, so they are of interest because of their clinical relevance in regards to osteoarthritis. To determine a suitable dose for use in these activation assays, chondrocytes were treated in vitro with varying concentrations of IL-6, IL-8, or OP-1, and changes in RNA transcripts of MMP-3, MMP-13, Col2A1, and Aggrecan were quantified using RT-PCR. In the case of IL-6, IL-8, and OP-1, it was determined that a dose of 100ng/mL media stimulated catabolism/anabolism. Chondrocytes were also examined using confocal microscopy following treatment with IL-6, IL-8, or OP-1 to determine if a correlation exists between the normal vs fibroblastic phenotypes and the activation status of the small G-proteins. Our initial hypothesis was that IL-6 and IL-8 would increase Cdc42 and Rac and decrease Rho activity, while OP-1 would have an opposite effect. Activity of the small G-proteins was determined through an affinity binding assay and subsequent western analysis. To date, our experiments indicate that treatment of the chondrocytes with IL-6 and IL-8 resulted in a decreased activity status of Cdc42 and Rac, which is contrary to the initial hypothesis. Studies to determine the effects of OP-1 and the activation status of Rho in response to all treatments are nearing completion.

title: The Impact of Front-End Usability Guidelines on Consumer Evaluations of E-Commerce Web Pages
abstract: This thesis examined the impact of usability guidelines and front-end web site design on consumer

aesthetic evaluations of e-commerce web sites and perceptions of the e-retailer. A detailed web site design guidelines framework was developed from an in-depth review of the usability, human factors, and human-computer interaction web design guidelines literature. Four web site design factors (background color, white space, thumbnail image location, and thumbnail image size) were selected and varied using this framework. In addition, as a secondary research focus, this study explored the impact of these front-end web site design factors on consumer trust, product preference, and purchase intention. Based upon the literature, a conceptual model was proposed which integrated usability and web site design with consumer web site evaluation, trust, purchase intention, satisfaction, and loyalty. Conjoint analysis methodology was then used to design web page prototypes. Results showed that subtle front-end web site design elements impacted consumer aesthetic evaluations of the web page and subsequent e-retailer evaluations, although individual-level analysis showed a high level of heterogeneity across respondents. Results also provided support for the conceptual model developed.

title: THREE PAPERS ON HEALTH AND DEVELOPMENT IN CHINA AFTER THE ECONOMIC REFORMS
abstract: This dissertation comprises three papers on health and development in China after the economic reforms initiated in early 1980s. The first paper analyzes the relationship between income inequality and health and provides some evidence that income inequality negatively affects population health. The second paper looks at determinants of children?s height and shows that a group of individual, household and community factors all play important roles in determining Chinese children?s health in the 1990s. The third paper investigates the under-nutrition situation in China along with intra-household inequality. A U-shape relationship is found between intra-household inequality and average household well being, which implies important policy applications. All three papers use the China Health and Nutrition Survey data.

title: Ranked search over structured and semi-structured data
abstract: Traditionally, relational database systems have been designed for precise queries over structured data, while information retrieval systems have been designed for more flexible ranked keyword search queries over unstructured (text) data. However, many new and emerging applications require data management capabilities that combine the benefits of database and information retrieval systems, e.g., e-commerce and content management applications. In this dissertation, we have proposed and initiated steps toward the larger goal of integrating relational database and information retrieval systems.
First, we consider the problem of ranked text search in relational databases, where the traditional ranking paradigms and techniques developed for stand-alone unstructured documents are not directly applicable. We thus propose a new ranking paradigm that uses structured data values to score the results of text search queries. Our experimental results on real and synthetic data sets show that we can support the new ranking paradigm efficiently in relational databases.
Second, we explore a novel problem of discovering rich relationships in databases based on user queries with text search and structural query conditions. Toward this end, we have introduced the notion of data topology and developed efficient algorithms for computing ranked topologies based on user queries. We have evaluated our algorithms using a real biological database, the Biozon database (http://www.biozon.org).

Third, we consider the problem of efficiently producing results for keyword
search queries over semi-structured XML documents. We present the XRANK system that is built to address the novel challenges for effective XML keyword search as apposed to HTML keyword search. Our experimental results show that XRANK offers both space and performance benefits when compared with existing approaches.

title: Exploring Negative Group Dynamics: Adversarial Network, Personality and Performance in Project Groups
abstract: This thesis reports on a two-phase study conducted to explore how negative relations can influence individual group member's performance when working on a group project, and how frequency of communication and personality can moderate this relationship. The first phase of the project examined the impact of negative relations and frequency of communication on performance in project groups. Results showed that group members disliked by others were less likely to perform well, albeit frequent communication with others could make a person more likable and consequently help him/her perform better. The second phase of the project investigated how the "Big Five" personality traits (conscientiousness, agreeableness, emotional stability, openness to experiences, and extroversion) and position in adversarial networks interacted to influence individuals' performance. The results showed that those individuals disliked by their team members for whatever reasons were less likely to achieve a good performance rating despite having such desirable personality traits as conscientiousness, emotional stability or openness to experiences.

title: Understanding Influenza Vaccine Behavior in Healthcare Workers: The Role of Information Seeking and Processing
abstract: In the United States, annual influenza epidemics kill approximately 36,000 people, seriously hospitalize 200,000, and cause substantial social and economic disruption. Fortunately, vaccination is considered an effective prevention method. However, despite recommendations by the Centers for Disease Control and Prevention (CDC), annually only 40% of healthcare workers are immunized against influenza. Such low rates present challenges not only to patient health, but also the delivery of medical services.
There is no magic formula for increasing influenza vaccine uptake among healthcare workers. Only a multi-faceted approach involving communication, cost controls and supply stability will achieve the desired result. This thesis focuses specifically on the role of vaccine communication in facilitating changes in immunization behavior. It argues that public health officials need to understand how healthcare workers make personal vaccine decisions and what informs those choices. Moreover, it provides commentary on the logistical, social and ethical issues this approach raises.
Overall, this thesis?s guiding question is as follows: What are the determinants of vaccine behavior among healthcare workers in various settings? Specifically, it focuses on how vaccine information is sought and cognitively interpreted, and how these actions influence immunization decisions. A model of risk information seeking and processing (RISP) is used as a guiding framework. This model explores motivations for information seeking and processing (i.e. systematic and heuristic), and their relationships to various components of behavior (e.g., attitudes, beliefs, and intentions). It posits that systematic processing, when paired with information seeking, is associated with a higher number of beliefs one considers, as well as

(ultimately) attitudinal stability and enduring behavior change. Given that influenza vaccination is a behavior repeated throughout one?s life, the focus on enduring change is particularly appealing.
This thesis is a ?first step? in exploring the relationship among vaccine information seeking and processing, and the aforementioned components of behavior. One hundred twenty-one in-person, telephone, and online interviews were conducted with physicians, nurses, paramedics and other groups within an urban community in central New York. Research goals included: (1) providing preliminary data on these cognitive behaviors, (2) developing measurements for several RISP model variables in need of further exploration, and (3) creating a foundation for future research with healthcare workers or other population groups. Study variables, derived from the RISP model, included: (a) information processing/seeking indicators, (b) preferred information sources, (c) perceived ability to find information, (d) salient beliefs about vaccination and (e) attitudes towards vaccine sources.
Overall, the data suggest that healthcare workers consider a variety of beliefs in deciding whether to be immunized. Beliefs associated with vaccination included the protection of personal health and patient well-being. Beliefs against immunization included lack of perceived risk for influenza, time constraints, and concern about side effects. Regarding information seeking, interviewees tended to favor health-related sources for vaccine information, including the CDC and their local health department.
Additionally, several measurements for heuristic and systematic processing were developed. Measures for systematic processing included relating the information to one?s responsibilities as a healthcare worker and considering one?s existing vaccine-related attitudes. Those for heuristic processing included: focusing on the length, clarity, and visual aspects of vaccine information. Finally, several theoretical and practical implications were discussed. Theoretically, two new variables were identified which may help delineate various gradients of information seeking beyond mere presence or absence. Practically, the data suggest that perceptions of information quality likely interact with vaccine-specific judgments in informing immunization decisions. Vaccine information that addresses key vaccine-related concerns and questions, as well as provides clear rationale for recommendations, will likely be most effective in achieving effectiveness and legitimacy.Cornell University

title: Mobilizing Restraint: Unions and the Politics of Economic Development in South Asia
abstract: While many studies examine the relationship between labor repression and economic development, few address the developmental implications of state-labor relations in democratic countries. Yet the rapid spread of democracy through the developing world highlights the need for such an investigation. In this dissertation, I show that in a democratic context, politically affiliated unions respond differently to changing local and global economic conditions than nonaffiliated unions. In particular, I argue that political parties are encompassing organizations that internalize the externalities associated with the protest of their affiliated unions. Thus, unions affiliated to major political parties respond to more competitive markets by restraining union protest and encouraging institutionalized forms of grievance resolution. In contrast, nonaffiliated unions are more likely to use worker frustration to ratchet up militancy against recalcitrant employers and encourage the use of extreme and violent forms of protest. I support these arguments with data gathered during 18 months of field research in four regions of South Asia: Sri Lanka and the Indian states of Maharashtra, Kerala and West Bengal. The findings of the dissertation call into question the conventional wisdom that partisan unions are inimical to economic development.

title: Effects of Matrix Metalloproteinase-13 on Extracellular Matrix Molecule Synthesis and Small GTPase Activation in Articular Chondrocytes
abstract: The degerative joint disease, osteoarthritis (OA), is a leading cause of disability in both humans and animals. OA involves the degradation of articular cartilage, which functions to dissipate tensile forces and cushion the joint1. Cartilage degeneration in OA is the result of multiple events including enzymatic degradation of matrix components and malfunction of the intracellular signaling pathways in chondrocytes 2. Traditionally, the catabolic cytokine interlukin-1, also called catabolin, has been used to induce an OA phenotype for in vitro experiments3, 4. Recent studies, however, indicate that matrix metalloproteinase-13 (MMP-13), also termed collagenase-3, is chiefly responsible for cartilage deterioration2, 4, 5. Though MMP-13 has been shown to play an integral role in OA, most studies to date have focused on proteoglycan cleavage mechanisms and the characterization of MMP-13 cell-surface binding and internalization 2, 3, 6-9. Thus it is the broad objective of this Honors Research Project to determine the effects of equine MMP-13 on the matrix molecule expression of chondrocytes and on the activation states of the small G-proteins of the Rho family (Cdc42, Rac, RhoA), and compare the results to those achieved after treatment with IL-1. To accomplish these aims, equine recombinant MMP-13 (eqrMMP-13) was cloned, inserted into a protein expression vector, and expressed as the active enzyme. To evaluate the expression of extracellular matrix molecules, chondrocytes were plated in monolayer, treated with eqrMMP-13, and total RNA was extracted and evaluated using quantitative RT-PCR. Assessment of the effect of MMP-13 GTPase activation was accomplished by treating chondrocytes in monolayer, retaining active GTP-bound GTPases from cell lysates using a GST fusion protein containing the binding domain of a down-stream target, in pull-down assays, and analyzing the retained proteins by polyacrylamide gel electrophoresis (PAGE) and western analysis, in addition to confocal microscopy. This study showed that MMP-13 induced similar changes in matrix molecule expression as IL-1 and significantly upregulated gene expression of the catabolic factor MMP-3, while down regulating gene expression of the anabolic factor collagen II B (Col2A1). Preliminary data from the pull-down assays indicate that IL-1 and MMP-13 decrease the activation status of Rac, and increase the activation status of RhoA. Confocal microscopy images support these findings. Together the results of this study suggest utilizing MMP-13 to induce the OA phenotype is an acceptable model of cartilage degradation in vitro. This may better mimic the native articular environment, and lead to more clinically translatable results than studies using IL-1 chondrocyte cultures.

title: Genetic and Phenotypic Characterization of Listeria monocytogenes Strains with Attenuated Virulence
abstract: Epidemiological studies have provided considerable evidence that Listeria monocytogenes strains differ in their ability and relative likelihood to cause human disease. Multiple mutations leading to premature

stop codons (PMSCs) have been identified in the key L. monocytogenes virulence gene inlA, which codes for a surface protein that mediates the entry of L. monocytogenes into host cells. Mutations leading to premature stop codons in inlA are associated with a reduced invasion phenotype in vitro, supporting the hypothesis that these mutations may also be responsible for attenuated human virulence. In order to further define the frequency of L. monocytogenes strains with reduced invasion capability, 207 isolates had previously been screened for ability to invade Caco-2 cells (Nightingale, unpublished). The inlA gene was sequenced for 27 isolates that showed attenuated ability to invade the epithelial cell line. Sequencing revealed mutations leading to PMSCs in 12 of the 27 isolates, including 2 novel mutations (PMSC types 5 and 7) and 3 previously reported mutations (PMSC types 1, 4 and 6). All but one of the isolates with confirmed PMSC mutations in inlA were isolated from food products or food processing plants. Our data support the hypothesis that L. monocytogenes isolates associated with food have attenuated invasion due to the presence of inlA PMSCs. Our data further suggest that sequence variation in inlA is an important factor that can be used to define L. monocytogenes that have a reduced ability to cause human disease. Since some strains with PMSCs in inlA were common in foods and environmental samples and were found in high levels in foods, it was hypothesized that these mutations may provide selective advantage, possibly outside a human host. Isogenic inlA PMSC strains were thus tested for their growth in rich medium and their resistance against common sanitizing agents. The results indicate that there is little difference in growth trends or sanitizer resistance between isogenic strains with and without inlA PMSC. It thus appears that inlA PMSCs do not enhance the ability of L. monocytogenes to grow in rich media or to be resistant to sanitizing agents.

title: Assessment of the Effects of Perinatal Choline Treatment on Attention and Reactivity to Reward Omission in a Mouse Model of Down Syndrome
abstract: Down syndrome (DS) is a genetic disorder caused by the trisomy of chromosome 21 in humans. Almost all individuals with DS also experience an early onset of Alzheimer?s disease (AD) and show similar cognitive and learning deficits. There are currently no treatments for these deficits in DS. However, choline availability during the perinatal period has shown to have long-term benefits on memory and attentional function. This study utilized a series of attentional tests that evaluated the benefits of perinatal choline treatment in Ts65Dn mice, an animal model of Down syndrome. Specifically, we used the ?Surprising Reward Omission? (SRO) Task in which an expected reward is omitted on 20% of the correct responses, to test attentional dysfunction and heightened error reactivity in these mice. Since previous SRO studies with Ts65Dn mice have shown an increase in locomotor activity and stereotypic behaviors such as jumping and grooming following reward omission, we supplemented our findings on overall performance with an analysis of video data. We hypothesized that the Ts65Dn mice will exhibit an exaggerated response to the omission of an expected reward relative to controls, which will be reflected by their poor performance on the SRO task, and that choline treatment will alleviate these dysfunctions. Our results indicated that the unsupplemented Ts65Dn mice had significant attentional dysfunction and reacted to incorrect responses with increased activity level. These abnormalities in Ts65Dn mice were normalized by perinatal choline supplementation. The reward omission did not significantly affect the performance of any of the mice (in terms of correct responses). Yet the elevated alcove latencies and omission errors in unsupplemented Ts65Dn mice provided some indication of increased reaction to reward omission. We expect the behavioral video analysis (in progress) to elucidate the exact nature of these reactions and the effect of choline treatment on arousal regulation and subsequent behaviors in Ts65Dn mice.

title: Applications of Metric Coinduction
abstract: Metric coinduction is a form of coinduction that can be used to establish properties of objects constructed as a limit of finite approximations. One proves a coinduction step showing that some property is preserved by one step of the approximation process, then automatically infers by the coinduction principle that the property holds of the limit object. This can often be used to avoid complicated analytic arguments involving limits and convergence, replacing them with simpler algebraic arguments. This paper examines the application of this principle in a variety of areas, including infinite streams, Markov chains, Markov decision processes, and non-well-founded sets. These results point to the usefulness of coinduction as a general proof technique.

title: CIVS: A Secure Remote Voting System
abstract: CIVS, the Cornell Internet Voting System, is the first implementation of a coercion-resistant, universally verifiable, remote voting scheme. This paper describes the design of CIVS, details the cryptographic protocols used in its construction, and illustrates how language-enforced information-flow security policies yield assurance in the implementation. The performance of CIVS scales well in the number of voters and offers reasonable tradeoffs between time, cost, and security. These results suggest that secure electronic voting is achievable.

title: Evolution vs. Intelligent Design in Consensus Protocols
abstract: Consensus is an important building block for building replicated systems, and many consensus protocols have been proposed. In this paper, we show that many consensus protocols can be derived from the same simple genes. We present these genes in the form of a skeleton algorithm that can be configured to produce, among others, three well-known consensus protocols: Paxos, Chandra- Toueg, and Ben-Or. Although each of these protocols specify only one quorum system explicity, we show that all employ a second quorum system. We use the skeleton algorithm to implement a replicated service, allowing us to compare the performance of these consensus protocols under various workloads and failure scenarios. From this we learn, for example, that weak leader election in Paxos unnecessarily causes performance degradation in certain failure scenarios.

title: Collective Inference on Markov Models for Modeling Bird Migration
abstract: We investigate a family of inference problems on Markov models, where many sample paths are drawn from a Markov chain and partial information is revealed to an observer who attempts to reconstruct the sample paths. We present algorithms and hardness results for several variants of this problem which arise by revealing different information to the observer and imposing different requirements for the reconstruction of sample paths. Our algorithms are analogous to the classical Viterbi algorithm for Hidden Markov Models, which finds single most probable sample path given a sequence of observations. Our work is motivated by an important application in ecology: inferring bird migration paths from a large database of observations.

title: On Distance Coloring
abstract: Call a connected undirected graph (d,c)-colorable if there is a vertex coloring using at most c colors such that no two vertices of distance d or less have the same color. It is well known that (1,2)-colorability is decidable in linear time, but (1,c)-colorability for c greater than or equal to 3 is NP-complete. Sharp (2007) shows that for fixed d greater than or equal to 2, the (d,c)-colorability problem is solvable in linear time for c less than or equal to 3d/2 and NP-complete otherwise. In this note we give an alternative construction that improves the upper time bound as a function of d for the case c less than or equal to 3d/2. The construction entails a generalization of the notion of tree decomposition and bounded treewidth (Robertson and Seymour 1986) to arbitrary overlay graphs, not just trees, which may be of independent interest.

title: Manipulation-resistant Reputations Using Hitting Time
abstract: Popular reputation systems for linked networks can be manipulated by spammers who strategically place links. The reputation of node v is interpreted as the world's opinion of v's importance. In PageRank, v's own opinion can be seen to have considerable influence on her reputation, where v expresses a high opinion of herself by participating in short directed cycles. In contrast, we show that expected hitting time --- the time to reach v in a random walk --- measures essentially the same quantity as PageRank, but excludes v's opinion. We make these notions precise, and show that a reputation system based on hitting time resists tampering by individuals or groups who strategically place outlinks. We also present an algorithm to efficiently compute hitting time for all nodes in a massive graph; conventional algorithms do not scale adequately. Our algorithm, which applies to any random walk with restart, exploits a relationship between PageRank and hitting time in random walks with restart. This relationship also provides novel insights into spam detection and PageRank computation.

title: Credibility Assessment of Misinformed vs. Deceptive Children

abstract: This is the first study to contrast how adults make credibility assessments about children who experienced a suggestive interview, children who had been coached to lie, and children who were telling the truth. Nine preschool children were interviewed about an event involving a minor infraction. Three of the children reported the truth, four were coached to lie, and two children reported misinformation as the result of a suggestive interview. Eighty-seven college students watched videotaped interviews of these nine children and assessed their credibility. Children who had experienced a suggestive interview were rated as credible as those who were telling the truth. Children who had been coached to lie were rated as less credible than the two groups of children. The results suggest that misleading information gets incorporated into children?s memory, thus arguing for a cognitive rather than social explanation of suggestibility. The implication for children's court testimony and jury decisions are discussed.

title: Diffusion of RFID and 3D Body Scanning for Mass Customization in Apparel Retail: A Consumer Study
abstract: RFID and 3D body scanning were identified as enabling technologies for consumer-centric mass customization in apparel retail. The objective of this research was to investigate consumer knowledge, interest and concerns towards the applications of RFID and 3D body scanning in apparel retail. Rogers? (1995) five factors for innovation diffusion, relative advantage, simplicity, compatibility, observability, and trialability and Bauer?s (1960) perceived risk provided the theoretical framework for the study. Consumer responses were utilized for demographic and behavioral segmentation to identify target markets for retailers deploying RFID and 3D body scanning for specific applications and investigate the consumer acceptance and business deployment of these technologies in apparel retail.
Testing prior consumer knowledge of the technologies indicated low knowledge level among consumers. Respondents with prior knowledge of RFID and 3D body scanning had significantly higher acceptance and lower privacy concerns associated with the technologies than respondents without prior knowledge indicating the need to increase the overall knowledge levels through improved literature in popular media and marketing campaigns. Other pre-test results indicated that frequent shoppers had a negative opinion towards apparel shopping suggesting the need to improve the overall shopping experience.
While there were no significant differences between male and female responses, female respondents identified size prediction as the most advantageous application of 3D body scanning. Respondents with higher income ($80,000+) and aged 40 or under were significantly more willing to accept RFID and 3D body scanning than the others. Strong acceptance of RFID and 3D body scanning use in a retail store was also observed for frequent shoppers and technology savvy respondents with significantly fewer concerns of price and privacy than other groups. Respondents indicated low willingness to pay a price premium to avail the benefits of RFID and suggested privacy and health concerns associated with RFID use while they were neutral about being scanned in undergarments.
A comparative analysis of the two technologies based on Rogers? five factors indicated that 3D body scanning had significantly higher means for relative advantage, simplicity, compatibility and trialability while there was no difference in observability between the two. The results indicated that 3D body scanning had significantly greater diffusion potential among consumers than RFID based on Rogers? factors, but both were evaluated favorably. A technology diffusion matrix was constructed based on prior literature and study results to indicate the current diffusion status of the two technologies based on consumer acceptance and business deployment. Recommendations were proposed to improve the overall knowledge of RFID through effective information dispersion to increase consumer acceptance by debunking myths regarding privacy and health concerns. The need to quantify the benefits of 3D body scanning in the apparel supply chain was identified as

a method to increase the overall level of deployment among businesses. A possible apparel retail scenario was recommended based on the results of the study integrating the applications of RFID and 3D body scanning to facilitate the diffusion of both technologies in the apparel industry for mass customization.

title: Synthetic Lethal Interaction Between ether-a-go-go Shaker and escargot Mutations in Drosophila
abstract: Escargot (esg) is a member of the snail family of transcription factors. Gain-of-function esg mutantions have been identified in previous studies as strong suppressors of seizure behavior in Drosophila models for epilepsy (Hekmat-Scafe et al. 2005). Recently, during a screen utilizing the ether-a- go-go (eag) Shaker (Sh) double mutant to identify genes that affect oxidative stress sensitivity, we uncovered a lethal interaction between gain-of-function esg mutations and the eag Sh double mutant The eag and Sh genes encode potassium channel subunits; epilepsy studies have revealed that eag and Sh are also mild seizure suppressors (Kuebler et al. 2001). The esg gene interaction is thus of great interest as it rescues seizure prone mutations while causing lethality in animals with increased seizure resistance. This study investigates the lethal interaction between eag Sh and esg to better understand its underlying mechanisms. Our results indicate that lethality is caused by severely impaired motor control in the adult. The animal exhibits many adult specific phenotypes, with distinctive synaptic phenotypes in adult and larvae. These results suggest that the critical period for esg-induced lethality is during adult development which agrees with the results of epilepsy studies.

title: Characterizing the Meiotic Failure and Transcriptional Aberrations Caused by Mutation of A-Myb in Mice
abstract: This project aims to understand the role of the transcription factor A-myb and its targets in spermatogenesis. If the project is successful, we will know how a mutation in the MybL1 gene leads to male sterility in the mouse. This information will give us a more detailed picture of the processes of meiosis and spermatogenesis, not just in the mouse but in all organisms with homologous genes and mechanisms.
I used bioinformatics to pinpoint genes which were being directly affected by A-myb using microarray data from 14 and 17 day wild-type and mutant testes. In addition, antibody staining for A-MYB protein was much lower in mutant mice, suggesting protein destabilization in mutants. Several differences in histone composition were observed through antibody staining. Expression of genes that seemed to be affected in the microarray were studied using real-time PCR to determine if they have overlapping roles in spermatogenesis.
The mutation in A-Myb affected many genes, most of which became downregulated. These affected genes may be transcribed by A-Myb directly or may be affected indirectly through expression of mediating genes. As more data is collected, we will be able to construct a model of A-Myb?s function in spermatogenesis and understand which genes play key roles in meiosis and spermatogenesis.
Ultimately, knowledge of the inner workings of meiosis and spermatogenesis will allow for advances in human and veterinary medicine. This knowledge is especially applicable to males who are sterile.

title: Environmental Stewardship in Agriculture: A Case Study of the NYC Watershed System
abstract: Agriculture has always been and will continue to be an important player in environmental integrity throughout the world. Because the manner in which humans manage agriculture has such serious implications on the environment and in turn people, it is imperative that some sort of environmental stewardship be practiced in agriculture. This research focuses on various methods of stimulating environmental stewardship (i.e. regulations, monetary incentives, etc.) and which method(s) might be the most suitable for agriculture. Management of agriculture in the New York City watershed system will function as a specific case for observing and evaluating how a socially-oriented management style incorporating such tools as partnerships, reciprocity and education can be formulated and implemented. Given the degree of environmental stewardship that has been fostered in the NYC watershed, the case is made that a socially-oriented form of environmental management can be incredibly effective at creating environmental stewardship in agriculture and ought to be applied on a broader scale.

title: A Comparative Study of Thomas Jefferson?s Travels to England and Their Influences on Monticello
abstract: Monticello, located in the city of Charlottesville, Virginia, was the estate home of the third President of the United States, Thomas Jefferson. It is also said to be one of the finest surviving examples of the English Garden Landscape in America, while also establishing the Standard American landscape style. Thomas Jefferson manipulated the landscape in conjunction with architecture years before Frederick Law Olmsted coined the term landscape architect. Monticello was influenced in many different aspects of architecture and landscape architecture from France, England, and Italy. A detailed analysis of his one-month journey throughout England reveals the influences of each estate on his classic English landscape garden tour. In 1786, Thomas Jefferson made sixteen stops throughout the United Kingdom, and by tracing and analyzing his steps, the thesis bridges the gap that exists regarding the current verbal and visual analysis of the English influence on Monticello. These stops included, Chiswick, Hampton Court, Twickenham, Esher-Place, Claremont, Painshill, Lord Loughborough?s Woburn Farm, Caversham, Wotton, Stowe, Leasowes, Hagley, Blenheim Palace, Enfield Chase, Moor Park, and Kew. The exploration of each park, estate, or garden using satellite images, photographs, photographic manipulation, and literature searches are used to reveal the visual similarities, differences, existing landscape forms and influences of English Estates and Gardens upon Monticello. Although there have been many articles, books, theses, and lectures written on the landscape of Jefferson?s Monticello, combining these with the visual analysis performed in this thesis provides the reader with a clearer understanding of the specific English influences on Monticello.

title: Effects of Surgical Sterilization upon Home Range Area of Suburban White-tailed Deer (Odocoileus virginianus) Population
abstract: As white-tailed deer (Odocoileus virginianus) populations continue to increase in suburban environments, local governments are considering ways to manage herd abundance and associated conflicts. Sterilization is one possible non-lethal method for controlling herd density, but little is known about the effects of sterilization on the behavior of female deer in suburban areas. We compared home range areas for a sample of sterilized (treated) female deer with home range sizes of reproductively-active females (controls).

Between January 2002 and March 2005, 61 deer were captured, radio-collared, and located weekly using radio-telemetry in the Village of Cayuga Heights, New York. Sixteen deer were surgically sterilized. Neither annual nor seasonal average home range areas were significantly different between the control and sterilized groups. In 2004, a subset of the study population (long-term resident deer present in both 2002 and 2004), did have significantly different annual average home range areas ($F= 5.946$, $df = 1$, $P < 0.05$). Control (27.7 ha) and sterilized (14.0 ha) long-term residents may have exhibited different home range use because of the behavior of control female deer caring for fawns during summer. The high site fidelity and survivorship of collared female deer indicates that sterilization could potentially have long-term effects, and may cause a slow population decline over several years. Continued resource utilization by sterilized deer would reduce the amount of resources available to reproductively-active immigrant deer.

title: A Comparison of Nearshore Fish Sampling Gears in Oneida Lake, New York
abstract: Sampling and assessment of nearshore fish communities is difficult due to the wide variety of habitats, substrates, and often complex structures. During the summers of 2005 and 2006, we conducted a comparison of ten different gear types, with the intent to develop a long-term sampling protocol of nearshore communities in Oneida Lake, NY. Gear types consisted of nine configurations of fyke nets and one seine. Fyke nets varied by frame size (large vs. small), mesh size (large vs. small), orientation (parallel vs. perpendicular), and the inclusion/exclusion of wings. Summers were broken into two sampling periods, during which 2 different sites were chosen for each of three major substrate types (sandy, rocky, and muddy) for a total of six sites. Student?s t-test indicated significantly higher species richness and total catch during sampling period two. However, few significant differences were observed in any net-to-net comparisons using Tukey?s Honestly Significant Difference (HSD). Catches of key sport fishes, such as smallmouth bass and largemouth bass were significantly higher in smaller meshed nets. In order to maximize ease, efficiency and accuracy, we recommend assessments of nearshore communities take place in sampling period two, using a combination of perpendicularly set medium frame fyke nets, with both large and small mesh sizes. Additional species, not caught by fyke nets, can be supplemented by seining at all sites.

title: Construction and Optimization of an Interferon Gamma Dipstick Assay for the Detection of Antigen-Specific Cell Mediated Immune Responses
abstract: Since 1957, when interferons were discovered, Interferon gamma (IFN-y) has played a crucial role as a diagnostic tool for both humans and animals. Because IFN-y is an antigen-induced protein produced by blood lymphocytes, namely CD4+ T-cells, it is considered the first and foremost form of defense that the host has against infections. Two pathogens that induce a cell mediated immune response (CMI) are Mycobacterium bovis (M. bovis), which causes tuberculosis (TB), and Mycobacterium avium paratuberculosis (Map), which is the causative agent for Johne's disease. Both diseases pose serious health and economic problems for livestock production, particularly cattle. Clinical signs of these diseases are not apparent during the early stages of infection nor are the levels of the mycobacterium high enough to detect. However, since exposure to tuberculin or Johnin antigen by skin testing induces a pathogen-specific CMI response with increased IFN-y, it has been suggested that this assay, in combination, might be useful in the diagnosis of TB or Johne's. However, while IFN-y assays are available, they have qualities that prohibit their routine use in the field. In this study, we

report the construction and optimization of a lateral flow assay for determining levels of IFN-y. This assay is also robust, easy-to-use and requires no sophisticated equipment, all qualities that are required for field performance. The format of the assay involves the immobilization of an IFN-y capture antibody onto plastic-backed nitrocellulose membrane using inkjet deposition. Then the sample is allowed to wick vertically up the membrane. Reagents to detect bound IFN-y are then wicked up the membrane and the printed lines of the capture antibody binding IFN-y antigen are developed. Thus far, this assay is sensitive to 1ng/ml IFN-y. When used in combination with skin testing, this IFN-y assay may prove useful in the diagnosis of early mycobacterium infection, and potentially other infections that induce a CMI response.

title: Prediction of Pregnancy Following Insemination of Dairy Cows
abstract: Plasma samples from dairy cows across two seasons (warm and cold) were re-assayed utilizing a more sensitive and uniform procedure in order to assess the use of progesterone and PGFM concentrations on the day of AI (Day 0) to day 8 in predicting future pregnancy status of the cow (pregnant vs. open, maintenance vs. loss of pregnancy). The effect of season on progesterone and PGFM serum levels was also assessed. Progesterone concentrations on the day of AI did not differ between cows inseminated during different seasons, nor did they differ between cows of different pregnancy statuses. PGFM concentrations on the day of AI also did not display any differences in cows of various pregnancy statuses, but there appeared to be a seasonal effect, with cold season cows maintaining higher PGFM levels than warm season cows. These results were unexpected, but do suggest that PGFM and progesterone levels on the day of AI may not be the best predictive factor for establishment of pregnancy.

title: Structure of BAR and PX Domains of Sorting Nexin 9 Reveals Cooperativity in Membrane Binding
abstract: Sorting nexin 9 (SNX9) belongs to a larger family of BAR-domain containing proteins. It is characterized by an N-terminal Src homology 3 (SH3) domain, a phox homology (PX) domain, and a Bin/Amphiphysin/Rvs-homology (BAR) domain. Together with clathrin and dynamin, it functions mainly in the endocytic pathway to sort proteins. SNX9 has also been shown to regulate receptor-mediated endocytosis of epidermal growth factor receptor (EGFR), by its interaction with Activated Cdc42-associated kinase-2 (ACK2), thus implicating a role for SNX9 in signal transduction.
Although the main cellular functions of SNX9 have been brought to light, little is known about the molecular mechanism by which this multi-domain protein participates in endocytosis and signaling. It is also unclear if and how the protein is regulated. In order to understand the interactions between the various domains of SNX9, we have crystallized and solved the structure of a shorter construct of SNX9 (here after called SNX9PX-BAR), which consists of only the PX and BAR domains. By analyzing this multi-domain structure and by conducting lipid- and vesicle-binding assays, we are able to gain a better understanding of how the two domains interact to influence the membrane binding ability of SNX9.
Our analysis of the structure of SNX9PX-BAR shows a dimeric BAR domain that is moderately curved. The BAR domain forms stable dimers via mainly hydrophobic interactions on the membrane surface. Membrane binding is most likely driven by electrostatic interactions between the PX-BAR domain and the negatively-charged plasma membrane. In addition, the PX domain of SNX9 shows high and specific binding affinity to PI(3)P, which is in high concentrations in early endosomes. Therefore, we propose that SNX9 might be

localized to both the plasma membrane and the early endosomes to participate in endocytosis and sorting of vesicles.

title: An Illustrative Narration of Hypnerotomachia Poliphili Through Gardens of Renaissance
abstract: In many historical eras, gardens have been created to convey ideas that more than just an immediate intention to give pleasure. Almost all great civilizations have produced designs for gardens, pools and fountains that have gone beyond the practical needs and creation of aesthetically pleasing sights and sounds.
This thesis studies the symbolism used in most gardens of the 16th century, inspired by the book Hypnerotomachia Poliphili, written in 1499 by Francesco Colonna. The title of the Hypnerotomachya Poliphili is compounded of three Greek words, Hypnos (sleep), Eros (love), and Mache (strife). The sleep of Poliphilo, the narrator and protagonist, is the occasion for the erotic dream that comprises the entire novel. In the process of finding his lover, the protagonist explains how he adores architecture and gardens, wanders around old graveyards and delights in sculptures. This thesis narrates the novel, Hypnerotomachya Poliphili, through photographs of Italian gardens designed as stages on which the story of Poliphilo takes place. One walks around the gardens of the renaissance and sees the episodes of the story quietly performed through the fountains, sculptures and the design and the layout of the gardens.

title: The Continuum of Metadata Quality: Defining, Expressing, Exploiting
abstract: Like pornography, metadata quality is difficult to define. We know it when we see it, but conveying the full bundle of assumptions and experience that allow us to identify it is a different matter. For this reason, among others, few outside the library community have written about defining metadata quality. Still less has been said about enforcing quality in ways that do not require unacceptable levels of human effort.

title: Analyzing Metadata for Effective Use and Re-Use
abstract: Using a commercially available visual graphical analysis tool, the National Science Digital Library (NSDL) has developed techniques to expedite evaluation of large batches of metadata. These techniques allow efficient and thorough review of large quantities of XML metadata, thus enabling the focus of limited resources on evaluation and manipulation tasks that are most important in our context. In the NSDL, metadata is evaluated for aggregation, but these techniques are applicable to any situation where batches of metadata need to be evaluated. This paper discusses the motivations for this approach and the techniques themselves.

title: Improving Metadata Quality: Augmentation and Recombination
abstract: Digital libraries have, in the main, adopted the traditional library notion of the metadata 'record' as the basic unit of management and exchange. Although this simplifies the harvest and re-exposure of metadata, it limits the ability of metadata aggregators to improve the quality of metadata and to share specifics of those improvements with others. The National Science Digital Library (NSDL) is exploring options for augmenting harvested metadata and re-exposing the augmented metadata to downstream users with detailed information on how it was created and by whom. The key to this augmentation process involves changing the basic metadata unit from 'record' to 'statement.'This work was funded by the National Science Foundation under grant 0227648.

title: "Too Filthy to be Repeated": Reading Sexualized Violence Against Enslaved Males in U. S. Slave Societies
abstract: "To Filthy to be Repeated": Reading Sexualized Violence Against Enslaved Males in U.S. Slave Societies is an exploration in the operation of male on male sexualized violence and resistance in the Atlantic World, specifically the United States. The work is concerned with the interaction of race, class, gender, and sexuality when a White male slaveholder sexually violates an enslaved Black male. The central task of this thesis is to properly re-read the history of slavery in the United States. Furthermore, this research project attempts to recover the silenced narratives of sexually assaulted enslaved males, while simultaneously asserting Black queer/quare re-reading as a fruitful theoretical and methodological tool for the scholarly and disciplinary labor of Africana Studies.
The thesis draws from two distinct, yet dialogical mediums for primary evidence--visual culture and slave narratives. The work attempts to place these antebellum sources in conversation with a Black queer/quare re-reading. I insist on "re-reading" instead of "reading", because these visual and written texts were not properly read the first time. Thus, a re-reading is required. It is at this point that this thesis seeks to make a critical intervention by exposing the sexual vulnerability of the Black male body and the Black individual and communal resistance against such transgressions. The first chapter, Slave Societies in Flux gives a brief socio-historical framework of slavery. It contextualizes race, class, and gender of the enslaved male as it relates to power and violence, particularly sexual violence. This chapter will address the "plantation" as a model for society, and acknowledge the importance of crop, region, colonial presence, era/period, urban v. rural, plantation size, enslaved population in determining power dynamics. Scenes of Inspection opens by acknowledging the Brazilian and Jamaican record of male-male sexual violence, and then moves to the visual record of enslavement, inspection, and sale by way of Trans-Atlantic crossings. The chapter is concerned with the construction and distribution of the Black male body in late 18th and early 19th Century visual culture. The engraving, March? d'esclaves by Laurent, and the paintings, The Slave Trade by Fran?ois-Auguste Biard and Slave Market by an unknown American artist are studied with a quare approach. This chapter deconstructs the scene of inspection and the White male pornographic gaze to build upon the structural insights of the first chapter. It demonstrates how the threat of male-male sexual violence operates within the realm of the visual. Like the pervasiveness of the inspection, the omnipotent threat of sexual violence is not only a Brazilian or Jamaican occurrence, rather, a Black Atlantic phenomenon. Resistance is the central theme of the chapters three and four, Re-reading Narratives. The purpose of these chapters is to explore the relationship between male-male sexual violence and resistance in the United States. I employ Harriet Jacobs?s Incidents in the Life of a Slave Girl and Frederick Douglass?s Narrative of the Life of Frederick Douglass, an American Slave and My Bondage and My Freedom in chapter three and four, respectively. Jacobs and the former enslaved male, Luke, make use of Black vernacular traditions to critique and resist U.S. legal discourse

and its support of sexual assault. Meanwhile, the prospect of male-male rape forces Douglass to retreat into a masculine safe space, which nurtures a gender progressive resistance. The thesis closes by contextualizing Black queer/quare re-reading as a scholarly endeavor within and natural to the Africana Studies project. The conclusion, The Art of Reading covers the overall theoretical implications and contributions of burgeoning Black que(e)rying of African American and American history, art, and literature. Lastly, considerations on the possible future directions of this research project are included.

title: Metadata Quality: From Evaluation to Augmentation
abstract: Accepted for publication in Cataloging and Classification Quarterly.The conversation about metadata quality has developed slowly in libraries, hindered by unexamined assumptions about metadata carrying over from experience in the MARC environment. In the wider world, discussions about functionality must drive discussions about how quality might be determined and ensured. Because the quality-enforcing structures present in the MARC world?mature standards, common documentation, and bibliographic utilities?are lacking in the metadata world, metadata practitioners desiring to improve the quality of metadata used in their libraries must develop and proliferate their own processes of evaluation and transformation to support essential interoperability. In this article, the author endeavors to describe how those processes might be established and sustained to support metadata quality improvement.

title: Tracheal Burning from Hot Air Inhalation
abstract: Burns in the trachea from inhaling hot gases are a common occurrence and threaten the recovery of

fire victims. Inhalation injury is also one of the most common causes of death, especially among children and the elderly. The thermal injury to the respiratory tract is usually limited to the upper respiratory tract, mainly the trachea. A better understanding of the interplay between transient temperature and injury distribution over the trachea may help to direct treatments in the future. Our goal is to model burns in tracheal tissue as a function of time, inhalation temperature, and inhalation velocity. The objective is to understand how variations in those variables affect tracheal injury. The velocity of air in the trachea varies as a function of time due to inspiration and expiration. As a result, the air temperature fluctuates in a cyclical manner. Since the burn concentration is a function of temperature, the extent of the burn rises as temperature increases with inspiration and remains constant as temperature decreases during expiration. Our model shows burn concentration is limited to the entrance to the trachea and the surface of the trachea.

title: Testicular Thermal Damage and Infertility from Laptop Use
abstract: Today, more laptop computers are being used on a daily basis than ever before. One of the health risks associated with extended, repeated use by men is that of testicular damage, or reduced spermatogenesis due to increased temperatures in the groin region. Naturally, the scrotum is maintained 2oC below standard body temperature. However, the combination of increased temperature due to leg positioning to support a laptop on the thighs, and the potential for temperatures of 60oC to be reached on the bottom, outer surface of the device [11] present a health risk. Although temperatures of 50oC are more common, they still contribute to a rise of approximately 0.6oC in addition to a 2.1oC increase which is already due to leg positioning alone. The direct contact between the thigh and testicles is a significant factor in this increase in temperature, as well as the laptop heat generation. In the future, potential methods of reducing heat conduction into the body may be mitigated by additional heat sinks, or fans which may reduce the effects of extended periods of laptop use.

title: Optimizing Release from Reservoir Microcapsules
abstract: Cytomegalovrius (CMV) retinitis is a common symptom of vision loss found in 20-30% of all acquired immunodeficiency syndrome (AIDS) sufferers. While there are no drugs that can cure permanent retinal damage by CMV, the drug ganciclovir has demonstrated efficacy against human cytomegalovirus infections and has been considered a first-line therapy in the treatment of sight-threatening cytomegalovirus infection in immune-compromised patients. The FDA-approved Vitrasert? implant, which is inserted at a localized region of the eye, is the current method of delivering ganciclovir intraocularly to patients with CMV. The Vitrasert? is a disc-like reservoir microcapsule that encapsulates ganciclovir in a polymer-based system. Maintaining a constant level of drug in the infected eye region is an important requirement in the design of this implant. The more constant the rate of drug release from the microcapsule, the more effective the drug will be. The objective of our model is to measure the diffusion of the ganciclovir release from the Vitrasert? into the surrounding tissue and to ensure toxic levels of the drug is not sustained. To accomplish this objective, the implant is simplified via axis-symmetry from a 3-D cylinder into a 2-D rectangle with homogeneous material properties, while the skin is reduced to a quarter-circle around our capsule. With our model, we are able to optimize the characteristics of the microcapsule to facilitate near constant drug release, which would be beneficial for many pharmaceuticals working with drug release from reservoir

microcapsules.

title: Laser Irradiation of Tumors for the Treatment of Cancer: An Analysis of Blood Flow, Temperature and Oxygen Transport
abstract: It has been shown that hypoxic tumor cells are resistant to radiation and that increasing tumor oxygen levels via laser-mediated hyperthermia treatment increases tumor cell radiosensitivity. Hence, studies of the effects of laser irradiation on tumor oxygen levels are of great interest, as they allow for the optimization of hyperthermia treatment. Accordingly, the main purpose of this experiment was to develop a finite element model to simulate the heat transfer due to laser irradiation of tumor tissue, the blood flow through a tumor capillary, and the effect of changing temperature on blood flow rates and oxygen delivery to tumor tissue. This was achieved by using finite element models in COMSOL Multiphysics. We employed two geometries based on those used in a simliar study by He et al. [1]: a tumor-containing breast model to simulate laser heating of the tissue and a capillary and tumor tissue model to simulate the effect of heating on blood flow and tissue oxygen concentration. By plotting partial pressure of oxygen as a function of radius at three different points in the tissue, we observed that the oxygen concentration was greatest near the inlet and lowest near the outlet (as expected), and that at all points in the tissue, heating increased the tissue oxygen partial pressure to about the same extent (0.75 ? 1 mm Hg). Furthermore, sensitivity analyses suggested ambient air cooling at the breast surface to be ideal and a laser intensity of 18000 W/m2 to be optimal for hyperthermia treatment. The model we developed was validated by comparison to a similar model and has potential for use in future studies on optimization of hyperthermia treatment.

title: Patch Immunization: Transcutaneous Vaccination for the Cholera Toxin and Optimization of Immunization Cycles
abstract: The main point of this analysis was to investigate the diffusion of the cholera vaccination through specific layers of the skin. The antigen was initially modeled through the skin directly to the blood stream. The antigen was also modeled with the presence of a network of Langerhans cells. There was a smooth concentration profile in the skin after one week of patch exposure in the absence of the LC network. However, there was discontinuity in the concentration profile when the LC network was present. The LC network functioned as a large enough sink term that the flux into the bloodstream was virtually zero. Therefore, we concluded that the LC network alone can create a cutaneous immune response. The LC network was enhanced with the presence of Imiquimod, a typical immune response modifier. The modifier increased the activity of the LC network, thus increasing the reaction rate of the LC cells. With Imiquimod there was a sharper discontinuity in the concentration profile at the LC network and the antigen flux into the blood stream is zero. The most effective enhancer tested was the MEMs microneedles, which increased the porosity of the skin and thus the diffusivity of the antigen through the skin. Contour plots of the skin showed absolute diffusion and consumption of the antigen into the LC network, while only partial consumption with the other enhancers tested. Concentration gradients were present in the ultrasonically and photo mechanically enhanced skin because they had weaker enhancing capabilities compared to the MEMs needles. The MEMs needles are the most effective in mass transfer, but are also the most evasive. Vaccines are usually given in cycles to increase the concentration of the antigen in the skin and bloodstream. When the patch was applied to the skin with

no enhancer, the maximum concentration was achieved after 2.3 days. However, the maximum concentration in the skin is achieved sooner with the various adjuvants. For example, when the patch is applied with MEMs needles, the maximal concentration is achieved in the skin only after 1.2 hours of exposure. Immunization cycles presented in Glenn et al were simulated to determine the approximate concentration of the antigen at the center of the skin needed for an immune response. This concentration is 0.0038 mol/m^3. Therefore, it was assumed that if the concentration in the skin is close to this value, then an immune response will be initiated. The immunization cycles for each adjuvant used were then optimized.

title: Magnetic Resonance Induced Heating in a Vascular Stent
abstract: It is standard hospital practice to remove metallic objects from patients prior to MRIs. Since magnetic resonance imaging employs changing magnetic fields, even everyday items such as jewelry or keys run the risk of overheating due to induced currents leading to Joule heating. A potential problem arises, however, when the metal is subcutaneously located in the form of a medical implant. The present study evaluated this scenario by using finite element analysis to model a vascular stent under the influence of a standard MRI field. COMSOL Multiphysics software was used to conduct finite element analysis on two different stent sizes, each in the presence and absence of blood flow. The stents were modeled as stainless steel (type 316L) with internal diameters of 5mm and 8mm, length of 40mm, and wall thicknesses of 0.18mm and 0.22mm. The tests revealed that under the influence of blood cooling, the stents modeled did not overheat or cause arterial damage. Specifically, the large stent resulted in a maximum temperature of 310.807 K and the smaller stent led to 310.230 K, each after 30 minutes of heating. In the unrealistic absence of blood flow, the large and small stents reached maximum temperatures of 318.851 K and 312.297 K respectively. Ultimately, given variance in blood flow the true solutions lie somewhere in between the blood perfusion and static flow models.

title: pH-Dependent Drug Delivery Systems
abstract: Gastric carcinoma, or stomach cancer, is a major disease in the world today. Although it only accounts for about 2% of all cancer cases in the United States, it is much more prevalent in nations such as Korea, Japan, Great Britain, South America, and Iceland. While the most common treatment for gastric carcinoma is surgery, there are chemotherapeutic alternatives including the application of doxorubicin, also known as Adriamycin?.
However, as with nearly all chemotherapy drugs, doxorubicin causes dose-dependent toxicity that results in severe biological side effects and, potentially, death. Many of the adverse effects of doxorubicin may be attributed to the fact that it is normally administered intravenously; thus, although the drug?s target is the stomach, the doxorubicin is systemically rampant. Hence, we have developed a delivery system for doxorubicin that we hope will limit the drug?s action to the stomach alone.
We begin with a means for encasing the doxorubicin inside two types of hydrogels whose diffusive properties vary depending on temperature and pH levels, such that diffusion may be maximized in the stomach and minimized at all other locations inside the gastrointestinal tract. This original design was modeled as a 1-D radial line to represent the spherical shape of the pill. After investigation, another design involving a hollowed out hemisphere was modeled and tested. Results comparison shows that the second design scheme is superior to the first both in outward drug flux and in the amount of drug able to be delivered.

Ultimately, results of the study showed that pH-dependent drug release can be attained at a steady and reliable rate, with significantly greater rates of release inside the stomach. However, we were unable to attain a clinically adequate amount of total doxorubicin release with our model designs. Still, it may be possible to achieve medically useful results with pH-dependent drug delivery systems given certain technological improvements in the future.

title: Lynah Rink: The Science of the Ice
abstract: Ice hockey is probably the most popular sports team at Cornell, easily selling out tickets to every game at the start of every year. Although eager fans study the team, plays, opponents, and results, it is doubtful that they pay any attention to the science behind the very ice the game depends upon. Our project seeks to look into the ice at Lynah rink, specifically the heat transfer processes involved in making the ice, maintaining it, and removing it in the off-season. We investigated how much time it would take to prepare the surface for ice hockey, how much time it would take to resurface the ice during a game, and lastly how much time it would take to melt all the ice and remove it during the off-season. We used a one-dimensional geometry with sixteen sections to model the eight layers of ice needed for the rink. Two sections represented one layer, equal to 0.3175 cm. Layers and boundaries were turned on and off depending on the part of the problem that was being solved for. Our initial results showed that it takes about four hours to place eight layers, equivalent to 2.54 cm of ice down on the rink. Conversely, it takes about five minutes for the 2.54 cm of ice to melt with the concrete slab heated. The resurfacing process, needed to be complete in less than fifteen minutes, was found by our model to take about six minutes. This value is subject to change from variation in the heat transfer coefficient and rink temperature, but our analysis found that even high values for these parameters still allowed resurfacing in a maximum of eight minutes. Melting was the least complex situation to model, and we found that it took about five minutes to melt the ice with the concrete heated to 60?C(333.15K).

title: The Effect of the Diving/Wet Suit on the Survival Time in Cold Water Immersion
abstract: In this study, we will compare the effect of normal clothes (assumed as bare skin) with effect of wetsuit in maintaining the core body temperature, produced by metabolic heat generations and blood flow heat generation, using COMSOL. A passenger is immersed in cold water after Titanic has shipwrecked, and the individual is waiting for rescue to come in time before his metabolic functions stop and die. We will compare two cases: with and without wetsuit on the passenger. Skin temperature or wetsuit temperature is assumed to be equal to cold water temperature, which is at 10 degrees Celsius, and the distribution of temperature throughout the body will be graphically shown as the time of body immersion in water increases. It is shown from the results that wetsuit can help maintain the normal core body temperature much longer than normal clothes/bare skin can in cold water immersion.

title: Oral Transmucosal Delivery of Fentanyl Citrate for Breakthrough Cancer Pain Relief
abstract: Episodes of breakthrough cancer pain are relatively common occurrences for patients undergoing cancer treatments. Characterized by pain unrestrained by traditional medications, these physical burdens impose a significant degree of suffering. In order to control and eliminate this pain, Actiq, a pharmaceutical lollipop, has been developed to provide rapid oral transmucosal delivery of fentanyl citrate, a potent medicinal narcotic. To elucidate the pharmacokinetics of the drug under various dosages, a computer model of fentanyl diffusion in the oral cavity was designed in COMSOL. Upon solving the model process, concentration profiles of fentanyl in the mucosa over time were developed for various dosages. Sensitivity analyses were also performed to determine the effects of several parameters on fentanyl diffusion. The resulting concentration profiles showed that peak concentrations of 0.00079 g/m3, 0.0016 g/m3, and 0.0032 g/m3 for 200 ?g, 400 ?g, and 800 ?g dosages, respectively, were achieved at approximately 800 seconds. Additionally, based upon the sensitivity analyses, the fentanyl solubility and the lollipop radial dissolution rate have the greatest impact on fentanyl concentration and diffusion. Future research can be performed to optimize the drug diffusion by altering these two parameters, ultimately yielding a more effective Actiq product.

title: Thermal Imaging and Analysis for Breast Tumor Detection
abstract: Breast cancer is the most common cancer among women, except for non-melanoma skin cancers. Women in North America have the highest rate of breast cancer in the world and the chance of a woman developing this cancer is 13% (ACS). Resulting deaths have been decreasing mainly due to early detection and increased awareness. This study analyzes the use of a thermogram as a potential method for breast cancer detection. The breast is evaluated by an infrared camera and a temperature profile is produced. Proper study of the image can show if a tumor is present. A computer simulation of this procedure was used to model the temperature profile and its change as certain parameters vary. Results show that in the present of a tumor, there is a difference in surface temperature of the breast. Input values such as tumor size, tumor location, heat transfer coefficients, and perfusion rates were varied to determine the reliability of a positive result despite differences in each unique breast from woman to woman.

title: Effects of Exposure to Plants and Nature On Cognition and Mood: A Cognitive Psychology Perspective
abstract: Two theories posit the restorative benefits of exposure to plants and natural settings, either in the form of stress reduction and improved mood, or through enhancement of cognitive performance, specifically attention processes. Research conducted on the latter area has used a wide variety of tasks to measure attention, often without consideration to underlying cognitive processes. The main purpose of this research was to examine the effects of natural stimuli on cognition and mood from a cognitive science perspective, using measures that assess specific underlying cognitive processes. The secondary objectives of the research were to explore the effect of natural stimuli on subjective well-being and examine whether different types of exposure would have distinct impacts on cognition and mood.
Four experimental studies were conducted in order to examine three exposure types: (1) window views of nature vs. buildings vs. control, (2) plants vs. other embellishments, and (3) two studies comparing the interaction with living plants to viewing pictures of plants. Dependent variables consisted of tasks used in

the cognitive sciences to measure underlying cognitive processes of inhibition, working memory, creative problem solving, and sustained attention. Verbal working memory was measured using the Backwards Digit Span task and the n-back task. Sustained attention was assessed using a vigilance task. Executive attention processes of inhibition and creative problem solving were measured by the Stroop Task, and either the Remote Associates Test or the Abbreviated Torrance Test for Adults, respectively. Subjective mood state was examined using the Profile of Mood States ? Short Form and the Positive and Negative Affectivity Scale.
Quantitative statistical analyses revealed the use of dependent measures assessing specific cognitive processes produces results different from previous operationalizations of attention employed in other studies. Window views of nature enhanced creative problem-solving performance more than the building view or ?no-view? control, but did not influence sustained attention. Participants exposed to plants versus other office embellishments did not show better performance on a working memory task. In the majority of the studies, mood state was unaffected. Overall, the results suggest that more precise operationalizations of attention are required.NASA - Kennedy Space Center

title: A Wavelet-Based Analysis of Commodity Futures Markets
abstract: The time horizon of decision-making is an essential dimension of economic problems but is difficult to explicitly define. In this thesis, we use time series analysis augmented by wavelet transform methods to precisely identify distinct time horizons in economic data and measure their explanatory power. This enables us to address three timely and persistent questions in the literature on commodity derivatives markets are addressed. First, are findings of long memory (fractional integration) in commodity futures price volatility spurious, following Granger?s conjecture? Yes, only two out of eleven commodities are characterized by true long memory and certain stochastic break models (e.g. Markov-switching) are found to be more plausible. Second, do large Index Traders such as commodity pools and pension funds increase futures price volatility through a large volume of trading activity? This appears to be true only for non-storable commodity contracts. Third, can we improve the accuracy of term structure models of futures prices by (i) including more state variables to better capture maturity and inventory effects, and (ii) filtering out what appears to be noise at the shortest time horizons? The results suggest that (i) three state variables is an optimal choice and (ii) estimates using filtered data are not improved and the noise may be economically meaningful.

title: Femoral Head Secondary Center of Ossification Development in a Canine Model of Hip Dysplasia: Onset, Mineral Density, and Shape
abstract: Developmental dysplasia of the hip (DDH) is characterized by joint subluxation, malformation, and early onset osteoarthritis. Little is known about how increased body weight and chronic, residual subluxation effect the course of early postnatal hip development. The objective of this research was to test the association of body weight and subluxation with femoral head mineral density and shape development, and with degeneration status at early adulthood. A longitudinal study was conducted using a canine model of DDH. Serial body weight, age at femoral head ossification onset, and femoral head coverage at 16 and 32 weeks were measured. Bone mineral density and secondary center of ossification (SCO) shape were evaluated using serial quantitative computed tomography at 7 ages between 4 to 32 weeks. Weight and shape analyses were conducted with 34 hips; mineral density analysis was conducted with 28 hips. Degeneration at 32 weeks

was assessed using necropsy and cartilage biochemistry. There was a negative association between birth weight and age at femoral head ossification onset; however, the association was likely due to skeletal maturity level rather than body weight per se. Lower birth weight subjects had greater femoral head coverage at 16 weeks. Greater birth weight was associated with greater probability of degenerative changes at 32 weeks. During growth acceleration, greater subluxation was associated with a lower mean SCO density, and, at 32 weeks, with a greater peak density and a greater area of high density subchondral bone in a more lateral location. Subluxation was also associated with a greater probability of degenerative changes at 32 weeks. At 14 and 32 weeks, greater subluxation was associated with a thinner SCO in the perifoveal region, the characteristic site of lesion formation. Increased thinness was associated with a greater probability of degenerative changes. At 32 weeks, greater subluxation was also associated with a bend in the SCO lateral to the perifoveal region. These results support the hypothesis that increased birth weight and chronic subluxation during the critical early postnatal growth period are sufficient to alter the course of hip development and result in measurable degenerative changes at adulthood.

title: Efficiently Exploring Architectural Design Spaces via Predictive Modeling
abstract: Computer architects rely on cycle-by-cycle simulation to evaluate the impact of design choices and to understand tradeoffs and interactions among design parameters. Although several techniques reduce time per individual simulation, efficiently exploring exponential-size design spaces spanned by several interacting parameters remains an open problem: the sheer number of experiments renders detailed simulation intractable. We attack this via an automated approach for building highly accurate and confident predictive models of design spaces. We collect simulation data incrementally, giving reliable estimates of model error on the full parameter space at each step of the building process. As validation, we perform sensitivity studies on memory system and microprocessor design spaces (conducting over 300K detailed simulations). Our models generally predict IPC with less than 1-2% error, even when trained on as little as 2% of the full design space. Further, our mechanism is orthogonal to techniques that reduce simulation runtimes. SimPoint [23] reduces the number of simulated instructions per experiment by 8-62?. We reduce the total number of simulated instructions by 50-200?. Combining our approach with SimPoint reduces the number of simulated instructions required to complete thorough design-space explorations by 1000-13,000?. Our approach has potential to quantitatively and qualitatively transform computer architecture research, enabling studies heretofore beyond our computational abilities.

title: Disputing Identity, Territoriality, and Sovereignty: The Place of Pomerania in the Social Memory of the Kingdom of Poland and the Teutonic Ordensstaat
abstract: This dissertation analyzes state-formation, the development of historical consciousness, and the construction of identities in medieval Europe. The source materials used to examine these topics are the records from a series of disputes between the Teutonic Knights and Polish and Pomeranian rulers during the thirteenth and fourteenth centuries. The first part situates these conflicts between the Teutonic Knights and their neighbors and benefactors in the context of the ethnic, religious, cultural, and political borderland society of the thirteenth-century south Baltic littoral. The second part examines how in the early fourteenth century these borderlands were transformed through a complex process of remembering and forgetting into

?bordered lands? of strictly demarcated political boundaries. The nature of the documentary evidence provides a unique opportunity to analyze how communities within Poland and the Teutonic Ordensstaat constructed their own views of their collective identity and history as well as how the views of these communities helped to inform and transform the views of the elites, who traditionally appropriated the role of preserving memories and propagating identities. In 1320 and 1339, in the aftermath of two periods of conflict between Poland and the Ordensstaat, the Papacy ordered legates to conduct inquires into the Polish kings? claims that the Teutonic Knights had illegally seized lands belonging to Poland. The lengthy testimonies of over 150 witnesses provide evidence about how representatives of different social and cultural groups in Poland thought about their role within the nascent Polish kingdom. Although the witnesses were asked by judges to respond to articles proposed by royal lawyers, the witnesses often took this opportunity to talk about whatever they felt relevant, sharing their personal memories of events, or memories which had been passed on to them by members of the various secular and ecclesiastical communities to which they belonged. They also presented reasons that went well beyond the scope of what they were asked ? their own views on ethnicity, history, law, and customs, and what role these played in defining where and what the Kingdom of Poland was, as well as who should be included within its boundaries.

title: Assessing the Financial Implications of Selling Dairy Digester-Generated Electricity to the Electric Grid
abstract: The primary objective in this project is to evaluate the economic implications of implementing an anaerobic digester with respect to the expenses and costs required to fund the system. The study assumed that all electricity generated by the anaerobic digester is sold directly to the grid. In this fashion, the study was able to determine the potential revenue when solely relying upon the market demand for electricity. By studying the previous market demand for electricity, it was found that the market demand of electricity ($/kWhr) in some cases can exceed the previously assumed value ($0.05/kWhr). From the LMBP prices collected (July 2005 ? August 2006), it was found that the market demand for electricity can sometimes exceed $0.18/kwHr. Additionally, the current analysis of historical market demand reveals that there is a steady increase in demand following each year. This further shows that the potential revenue that can be generated by selling AD generated electricity to the grid can be greater than previously expected. To further utilize this increase in expected revenue, it is higher recommended to determine potential options to increase biogas production rates to generate higher annual revenues beyond that of the annual expenses required to operate the system. The current analysis shows that food substrates have the potential to dramatically increase biogas production rates and revenue generation beyond the respective annual expenses required. This has the potential to help increase the annual net gain, and reduce the simple payback period. Additionally, the data reveal that biogas production rates can help to determine a proper engine-generator set to use. Assuming that the desired engine-generator set is unavailable, the current study shows that a multiple engine-generator set has the potential to produce the same amount of electricity and revenue as the desired engine-generator set.

title: EFFECT OF FEEDING CORN SILAGE BASED DIETS PREDICTED TO BE DEFICIENT IN EITHER RUMINAL NITROGEN OR METABOLIZABLE PROTEIN ON NITROGEN UTILIZATION AND EFFICIENCY OF USE IN LACTATING COWS
abstract: Due to concern over nitrogen (N) emissions, this study attempted to evaluate dietary approaches to reduce N excretion by dairy cattle. Knowledge about potential N sources that were either unaccounted for or under-predicted by CPM Dairy and the Dairy NRC (2001) was used to formulate rations that were much lower in crude protein (CP) than typically fed to dairy cattle but would potentially not decrease production. Specifically, the three diets fed were predicted to have: (1) positive rumen N and metabolizable protein (MP) balances (Diet P) (2) negative MP balance and positive rumen N balance (Diet N), or (3) negative rumen N balance but positive MP balance (Diet T) as predicted by CPM Dairy version 3. The objective of this experiment was to determine whether, and to what extent, the decrease in predicted ruminally available N and MP supply would affect milk production.

Eighty-eight multiparous lactating Holstein cows (83 +/- 20 DIM), were blocked by average daily milk yield to 50 DIM and parity and assigned to three diets differing in N content or predicted rumen degradability of the feed N. The diets were formulated with CPM Dairy V3 using library values for all feeds except corn silage where actual chemical, digestibility, and degradation rate values were determined and used. The diets (DM basis) consisted of approximately 50% corn silage, 2% wheat straw and 48% of a diet specific ingredient mix and were formulated for 22.2 of kg DMI. Actual diet CP levels were 16.7, 14.2 and 14.3% for Diets P, N and T, respectively. The predicted CPM Dairy rumen N balance at the formulated DMI was 29 and 27 g for Diets P and N and negative 39 g/d for Diet T, whereas the predicted MP balance was 263 and negative 145 and 91 g/d for Diets P, N and T, respectively. Monensin was included in the diets at a formulated intake of approximately 300 mg per cow per d and somatotropin was administered per label.

Actual DMI for cattle fed these treatments were 25.7, 25.5 and 24.2 kg/d for Diets P, N and T, respectively and were significantly lower for Diet T. Actual milk yield was 45.0, 42.6 and 43.3 kg/d and 3.5% FCM was 38.1, 36.5, and 36.4 kg/d for cows fed Diets P, N and T, respectively and was significantly lower for cows fed Diets N and T. Milk protein percent was not affected by diet; however, milk protein yield was significantly greater for cows fed Diet P due to the difference in milk yield. Plasma urea N concentrations were 11.31, 8.40 and 7.13 mg/dl for cows fed diets P, N and T, respectively and were different and paralleled the rumen ammonia levels of 8.32, 6.58 and 5.84 mg/dl. Milk fat depression (MFD) was observed in all cows and was not affected by treatment, and the average milk fat levels were 2.67, 2.68 and 2.54% for diets P, N and T, respectively. To determine if monensin was partially responsible for the MFD, monensin was removed from the diets of approximately half of the cows on treatment once they had finished the experimental period. Removal of monensin resulted in a 30% increase in milk fat percent, and milk protein content was not affected. Calculated milk N:intake N ratios for the three treatments were 0.31, 0.33 and 0.36 for Diets P, N and T respectively.

The results of this study suggest that more productive N is available than currently predicted by either CPM Dairy and the Dairy NRC (2001). Understanding where these differences exist would allow for feeding less CP to dairy cattle and decreasing N emissions to the environment. It may also be a profitable strategy for dairy farmers, as they would be able to reduce their purchase of costly protein feeds, but that was not demonstrated in this study, primarily due to the severe milk fat depression that decreased the economic value of milk. However, ration cost was not a concern for this experiment, and that aspect can be considered when implementing feeding strategies stemming from this research.

title: MULTISCALE MODELING OF SOLIDIFICATION OF MULTI-COMPONENT ALLOYS
abstract: Modeling solidification in the micro-scale is computationally intensive. To overcome this difficulty, a method combining features of front-tracking methods and fixed-domain methods is developed. To explicitly track the interface growth and shape of the solidifying crystals, a front-tracking approach based on the level set method is implemented. To easily model the heat and momentum transport, a fixed-domain method is implemented assuming a diffused freezing front where the liquid fraction is defined in terms of the level set function. The fixed-domain approach, by avoiding the explicit application of essential boundary conditions on the freezing front, leads to an energy conserving methodology that is not sensitive to the mesh size. Techniques including fast marching, narrow band computing and adaptive meshing are utilized to speed up computations. The model is used to investigate various phenomena in solidification including two- and three-dimensional dendrite growth of pure material and alloys, eutectic and peritectic solidification, convection effects on crystal and dendrite growth, planar/cellular/dendritic transition, interaction between multiple dendrites, columnar/equiaxed transition and etc.
Interaction between thousands or even millions of crystals gives the overall behavior of the solidification process and defines the properties of the final product. A multiscale model based on a database approach is developed to investigate alloy solidification. Appropriate assumptions are introduced to describe the behavior of macroscopic temperature, macroscopic concentration, liquid volume fraction and microstructure features. These assumptions lead to a macroscale model with two unknown functions: liquid volume fraction and microstructure features. These functions are computed using information from microscale solutions of selected problems. A computationally efficient model, which is different from the microscale and macroscale models, is utilized to find relevant sample problems. The microscale solution of the relevant sample problems is then utilized to evaluate the two unknown functions (liquid volume fraction and microstructure features) in the macroscale model. The temperature solution of the macroscale model is further used to improve the estimation of the liquid volume fraction and microstructure features. Interpolation is utilized in the feature space to greatly reduce the number of required sample problems. The efficiency of the proposed multiscale framework is demonstrated with numerical examples that consider a large number of crystals. A computationally intensive fully-resolved microscale analysis is also performed to evaluate the accuracy of the multiscale framework.

title: Wide angle x-ray scattering probes chain order and identifies liquid-liquid phase coexistence in oriented lipid membranes
abstract: Committee members: Sol M. Gruner, Carl Franck, James P. Sethna, Gerald W. FeigensonWe have used grazing incidence wide-angle x-ray scattering (GIWAXS) on oriented lipid multilayers to measure chain order and to examine liquid-liquid coexistence in the system DOPC/DPPC/cholesterol, a model for the outer leaflet of the cell plasma membrane. Coexistence of liquid-disordered (Ld) and liquid-ordered (Lo) domains is thought to be related to “rafts” in the cell membrane, cholesterol-rich lipid heterogeneities which provide platforms for protein sorting. Many of the methods used for measuring liquid-liquid coexistence in model membranes require a potentially perturbing probe, while x-ray scattering is probe-free. In unoriented (powder) x-ray data, scattering from the Ld and Lo phases looks very similar, whereas in GIWAXS patterns from oriented samples, these phases are easily distinguishable because of the differences in their chain orientational order. By using a simple analytical model to relate the GIWAXS data to the chain orientational

distribution, we fit our data to obtain the average chain orientational order parameter, Smol. While this type of analysis has been well-used for liquid crystals, it is not commonly applied to model membrane systems. For DOPC/cholesterol and DPPC/cholesterol mixtures, composition and temperature dependent trends in Smol determined by GIWAXS are consistent with earlier NMR data. Addition of 40% cholesterol to liquid-phase DPPC or DOPC more than doubles Smol. In addition to measuring chain orientational order parameters for binary mixtures of DOPC/cholesterol and DPPC/cholesterol, we have measured GIWAXS for ternary mixtures where fluorescence microscopy and NMR indicate the coexistence of Ld and Lo phases below the miscibility transition temperature, Tmix. In order to fit to the GIWAXS data for these mixtures at low temperature, we required two values of Smol, which we interpret as evidence of coexisting Ld and Lo phases. Our Tmix values based on x-ray work agree reasonably (to within the 5-10 C temperature steps used) with the Tmix values based on the NMR and microscopy work of Veatch et al. (Veatch and Keller, 2003b; Veatch et al., 2004; Veatch et al., 2007b). This approach provides a new method for examining phase coexistence in model membranes without the need to add a potentially perturbing probe.NIH Molecular Biophysics Training Grant, NSF MCB-0315330, NIH GM 44976, NSF DMR-0225180, DOE DE-FG02-97ER62443

title: Multi-scale Computational Techniques For Design Of Polycrystalline Materials
abstract: Your submission was rejected by Pattie Place:I am rejecting because on page 95 there is too much white space.
But Page 95 is at the end of a chapter?Microstructures play an important role in controlling distribution of properties in engineering materials. It is possible to develop components with tailored distribution of properties such as strength and stiffness by controlling microstructure evolution during the manufacturing process. When forming metallic components by imposing large deformations, mechanisms such as slip and lattice rotation drive formation of texture in the underlying polycrystalline microstructure. Such microstructural changes affect the final distribution of material properties in the component. By carefully designing the imposed deformation, one could potentially tailor the microstructure and obtain desired property distributions. This thesis focuses on development of novel computational strategies for designing deformation processes to realize materials with desired properties. The techniques presented are an interplay of several new tools developed recently, such as reduced order modeling, graphical cross-plots, statistical learning, microstructure homogenization and multi-scale sensitivity analysis. The primary outcomes of this thesis are listed below:
1. Development of reduced-order representations and graphical methodologies for representing process-property-texture relationships.
2. Development of adaptive reduced-order optimization techniques for identification of processing paths that lead to desirable microstructure-sensitive properties.
3. Development of homogenization techniques for predicting microstructure evolution in large deformation processes.
4. Development of multi-scale sensitivity analysis of poly-crystalline material deformation for optimizing microstructure-sensitive properties during industrial forming processes.
The framework for design of polycrystalline microstructures leads to increased product yield in industrial forming processes and simultaneously allows control distribution of properties such as stiffness and strength in forged products. Multi-scale design problems leading to billions of unknowns have been solved using parallel computing techniques. The computational framework can be readily used for selecting optimal processing paths for achieving desired properties. The methodology developed is a fundamental effort at providing detailed deformation process design solutions needed for controlling properties of performance-

critical hardware components in automotive, structural and aerospace applications.

title: Using General-Purpose Processor Cores as Prefetching Engines in Chip Multiprocessor Architectures
abstract: Scaling the performance of applications with little thread-level parallelism is one of the most serious impediments to the success of multi-core architectures. At the same time, the long latency of memory accesses represents one of the largest performance bottlenecks for individual program threads. As a result, a typical microprocessor spends a significant amount of time waiting for data to be delivered from memory instead of performing useful computation. Fortunately, it is often possible to guess which memory data will be needed by a program thread in the near future. Various hardware and software prefetching techniques have been developed to fetch critical data before they are requested by the processor. This way prefetching can eliminate processor stalls otherwise induced by the slow response from the memory system. The main contribution of this dissertation is the development of two techniques that utilize extra cores of a chip multiprocessor (CMP) as prefetching engines to increase the performance of single program threads. The proposed approaches effectively leverage the execution capabilities of chip multiprocessors to compute data addresses that are likely to miss in the cache and prefetch them ahead of program thread load requests. I demonstrate the effectiveness of the proposed approaches by performing cycle-accurate simulations of a chip multiprocessor consisting of two four-way superscalar cores running the single-threaded SPEC CPU2000 benchmark suite. The proposed mechanisms provide significant performance improvements over a baseline that already includes an aggressive hardware stream prefetcher. A comparison with other multi-core prefetching mechanisms from the literature shows that the techniques proposed in this dissertation provide competitive performance, incur less energy overhead, and require considerably simpler hardware support.

title: DESIGN OF A FOUR-ROTOR AUTONOMOUS HELICOPTER FOR VEHICLE BASED PHASED ANTENNA ARRAYS
abstract: Autonomous flying vehicles (AFVs) have applications ranging from police surveillance to military synthetic aperture radar mapping. In many such applications, AFVs must transmit large quantities of data to a distant base station. Since this can be difficult without the ability to place large, high-gain antennas on small vehicles, we propose the idea of flying the vehicles in formation while transmitting and forming a phased-array antenna with one element on each vehicle.
To determine the feasibility of this concept, we studied the constraints imposed both by antenna theory and by present AFV technology. While position errors in the array can cause a great reduction in antenna gain, good position sensing can allow phase compensation to recover most of the ideal case antenna gain even with significant position error.
Two electrical team members and one mechanical member worked together to produce a four-rotor helicopter-type AFV which was tested as well as modeled in simulation. The physical vehicle demonstrated autonomous hover and bench tests indicated that it should have 0.8 g excess thrust beyond hover and 10 minute battery endurance. Simulation of a formation of several of these AFVs showed very promising improvements in predicted AFV communication range (in one example, 9.6 dB gain for an array of ten in 10 MPH wind, for a range improvement of a factor of 3, representing 100 kilometer range with a total array power of only 1.5 Watts). Future work may include an actual physical test of formation flight of several AFVs, possibly even with a phased array antenna system, or at least with an antenna simulation based on real position data. This latter simulation was already performed on data from formation flight simulations, provided by Honeywell, of their Organic Aerial Vehicles (OAVs), showing promising antenna array gain results.

title: COMPUTATIONAL AND EXPERIMENTAL APPROACHES RELATED TO NITROUS OXIDE EMISSIONS AND ECONOMIC ANALYSIS OF PRIVATE AND SOCIAL RETURNS FROM MAIZE FERTILIZATION
abstract: Continued research and development of computational methods are needed to effectively address both environmental and economic issues related to nitrogen (N) use for maize fertilization. This research consists of three major inter-related components. The first constitutes an experiment in Willsboro, New York to estimate the impact of management practices, especially tillage and timing of N application on nitrous oxide (N2O) emissions for clay loam and loamy sand. The second component includes the use of N2O emissions, and soil physical and chemical data collected from the Willsboro experiment to 1) calibrate the Precision Nitrogen Management (PNM) model, 2) determine the N2:N2O ratio from partial N budgets and incorporate it into the PNM model for N2O losses estimations, and 3) evaluate different combinations of process representations of the PNM model. The final component involves an integration of the PNM model and economic analyses by 1) simulating long-term yield and environmental N losses for maize production on three textural soils, and 2) estimating private and social returns based on PNM-simulated data. Nitrous oxide losses averaged four times higher on the clay loam than the loamy sand soil. Under no-tillage, full fertilizer application at planting resulted in 4.7 and 2.3 kg N ha-1 greater cumulative N2O losses than starter-only fertilizer application on maize after grass and continuous maize plots, respectively. Nitrogen management critically affects the extent of N2O losses, particularly for fine-textured soils under no-tillage, and must be an important consideration in soil and crop management for greenhouse gas (GHG) reduction. With the process complexities in the soil-plant-atmosphere system, modeling of N2O losses was challenging, especially for short-term periods. The incorporation of the biological aspects of the denitrification process is important to capture the dynamics involved in the production of N2O fluxes. Timing of N application affected optimum N rates depending on soil type and weather conditions. The economic modeling effort provided a framework for computations of revenue that incorporates environmental impacts of N fertilizer management. A more sophisticated approach is necessary to 1) increase PNM model accuracy, and 2) refine the calculations on environmental losses and associated damage costs for practical farm application.

title: Essays in Labor and Organization Economics
abstract: The following dissertation is a collection of three independent essays. The first two essays contribute to the literature on Organization Economics. The third essay contributes to the literature on data confidentiality.
Essay 1, "Turnover as a Gateway to Symmetric Information," explores high-ability turnover in highly competitive labor markets. Why do workers who are successful at a given firm decide to leave? Essay 1 asserts that such movement is driven by the presence of asymmetric information. In particular, it is shown that when competing firms have less knowledge of a worker?s ability than his current firm, there exists an incentive for high-ability workers to leave their current job in pursuit of a higher wage. Such an incentive generates a set of testable predictions. The predictions are tested using the personnel records from the management of a medium-size firm in the US financial services industry. The data is consistent with the theory.
Essay 2, ?Piece-Rates, Salary, Performance and Job Level,? explores the effect of monitoring and hierarchy on compensation structure. Previous work has shown that monitoring worker effort is more difficult at

lower levels of the hierarchy, and, simultaneously, that compensation should rely more on salary payments than piece-rate payments when effort is more difficult to monitor. Essay 2 formalizes these ideas in a simple model of moral hazard. The model generates a set of predictions about how salary, bonus and performance should vary across levels of the hierarchy. The predictions are tested using the same data as Essay 1 and strong support is found.
Essay 3, ?Synthetic Data and Risk of Disclosure,? explores how well synthetic data protects confidential data. Using a unique Census dataset and 4 synthetic implicates, the risk of disclosure is found to be quite small. In a secondary analysis, the effectiveness of distance-based and probabilistic re-identification methods are also explored. Contrary to previous experiments it is found that probabilistic re-identification outperforms distance-based. Further, it appears that the difference in performance is driven by the number of matching variables: as more matching variables are added, the success rate of probabilistic matching increases more quickly.

title: BIOLUMINESCENT ACTIVITY IN THE MATING AND ANTIPREDATORY BEHAVIOR OF A MARINE OSTRACOD (CRUSTACEA, MYODOCOPIDA)
abstract: About an hour after the sun sets a complex and ritualized light show of precise, vertically placed luminescent pulses erupts over the shallow grassbeds of the western Caribbean throughout the year. These are the most complex displays known in marine systems. Displays consist of repeated trains of secreted bioluminescent pulses in a specific pattern ejected into the water column for courtship by male Vargula annecohenae, small (<2mm) myodocopid ostracod crustaceans. Quantification via the use of image intensification and infrared videography shows that each 40-cm long luminescent display train consists of a stationary phase of 3 (usually) brighter, longer pulses placed close together, followed by a helical phase of about a dozen evenly placed dimmer, shorter pulses secreted by an individual male rapidly spiraling upward. The operational sex ratio in the display grounds above the grassbeds is highly skewed toward males (>175:1). Each participating male is capable of 1) initiating a luminescent display train, 2) entraining on another displaying male in loose luminescent synchrony, and 3) ?sneaking? silently on a luminescing male, and can switch among these three tactics during a single train. Which alternative mating tactic is chosen is predicted by the orientation and distance of the responding male from the initial courtship display at the start of that tactic. Unlike fireflies, females do not respond with luminescent signals of their own. Instead, by using a light-emitting-diode array to mimic a male display, I show that females respond to and intercept the intermittent luminescent displays by compensating their trajectories between each light pulse. Besides courtship, all individuals of V. annecohenae (males, females, and juveniles) respond to predation attempts by their nocturnal predators by releasing enormous quantities of luminescence. Since individuals are distasteful to their predators, the signals probably function as aposematic signals, but also as lures for predators of an attacker (burglar alarm). Based on photomultiplier tube recordings of 1) courtship displays, 2) antipredation displays, and 3) total luminescent available, a male could produce nearly 500 courtship trains or 4 major antipredation displays from its existing stores.

title: Adopted Colors: Domesticity and Foreign Nationalism in Elizabeth Barrett Browning and George Eliot
abstract: James Eli Adams, Dorothy Mermin, Harry E. ShawThe dissertation explores the trope of lost and recovered children in the narratives of nationalism by Victorian women writers excluded from political participation. Bringing together the narratives of fragmented family and divided allegiance, my project focuses on how women writers constructed an imagined connection with other people's nationalism by subverting deracinated fantasy to explore the tensions between the individual and racial inheritance. Examining the cultural construction of Italians, Gypsies, and Jews in the British nineteenth century, this dissertation investigates the "timeless" fantasies of artistic freedom, liberation, and tolerance associated with landless "dark Others" that contrast with their historical marginalization in England. What appeal to Barrett Browning and Eliot, are not escape from racial inheritance, but the pressing duties of the lost child to preserve history and identity, as she negotiates a role of political leadership that constrains her private choices.
Inspired by the struggle of her adopted country to overthrow Austrian rule, Elizabeth Barrett Browning envisioned a national future of Italy in Casa Guidi Windows. Following the fictionalized travel writing of Anna Jameson and Arthur Hugh Clough that attempts to avoid politics in favor of art, I argue that by constructing kinship through Anglo-Italian literary tradition, Barrett Browning advocates the Italian revolutions of 1848 as liberal politics demanding English sympathy through spiritual inheritance. Conversely, Gypsies shed their ?spiritual appeal? to become racial figures, through the rise of Gypsy ethnography, popularized by George Borrow and later the Gyspy Lore Society, who mapped the linguistic and racial origins of the English Romany. The claim to race and history provides no solution for survival in Eliot?s long poem The Spanish Gypsy. Although Fedalma?s interstitial role does not bridge Gypsy and Spain, in Eliot?s last novel

Daniel Deronda, the adopted child's claim to racial memory depends on the disinherited daughter. Deronda's origins are legitimized through his reunion with his mother, but the process of inheriting Judaism rests on the tradition of Jewish women writers such as Grace Aguilar, who argued for women's religious education. The "exotic Jewess" Mirah resists conversion and reconstructs racial identity through the memory of her mother's spiritual instructionFulbright, KAEC, IIE

title: Of Contradictions and Tautologies
abstract: According to one standard semantic definition of a contradiction, a sentence is a contradiction if (and only if) it is false in every model, whereas a sentence is a tautology if (and only if) it is true in every model. This dissertation explores three reinterpretations of these definitions, each of which seeks to extend the coverage of these definitions to new phenomena in natural language. The first reinterpretation excludes all models in which a term is undefined, and is used to classify certain Existential There Sentences as either contradictions or tautologies. The second reinterpretation excludes the very few models in which a sentence whose subject is a but-phrase that is headed by a non-universal determiner is true. The final reinterpretation requires that we shift our focus from models, to the more inclusive concept of an interpretation, and classifies a sentence whose meaning is compatible with only one interpretation that is always false as a contradiction. An example of this strategy is any statement of support for the position that all quantification is restricted in natural language, e.g. I am not quantifying over everything. The dominant focus of these reinterpretations has been the behaviour of the data in the sanctioned models (or interpretations). A strategy, I will argue, that does not yield nearly as much insight into the semantic properties of natural language as a close study of these constructions in the excluded models (or interpretations). The topics covered include the odd truth value assignment to Existential There Sentences in which a term is undefined, the influence of Grice's maxims of conversation on the distribution of DPs in but-phrases, and the possibly related phenomenon of sentences in which the subject is modified by a sentence initial only, and finally, the impossibility of expressing the content of the view that all quantification is restricted in natural language.

title: Decolonizing Waterscapes in Indian Country: American Indian Struggles for Water and the Making of the American Empire
abstract: Graduate Committee: Philip McMichael, Angela Gonzales This thesis examines the social, institutional, and discursive barriers facing American Indian struggles to access and manage water today. It argues that these barriers constitute a form of "accumulation by dispossession" whereby Indian communities are marginalized in their capacities to reclaim control over the waterscapes that have sustained them for generations in order to serve the ongoing economic growth and development of the Western United States. To understand the origins of these dynamics this thesis examines the history of how the U.S. formed and operationalized its continental empire in the 19th century in a world historical context. It shows how U.S. imperialism critically hinged on the development of new forms of knowledge production, technologies, and tactics of rule for remaking American Indian nations and Western waterscapes. These historical processes enabled the settlement, economic development, and consolidation of the U.S. nation state. They were constituted through transnational exchanges with other colonial regimes and with significant fostering from the U.S. state. These colonial knowledge regimes, discourses, and policies solidified into durable social and

political institutions at the height of global imperialism between the 1870s and the first few decades of the 20th century and continue to structure American Indian struggles for water today. Through this history we will understand how and why Indian nations were dispossessed of and marginalized in their rights to access and manage water. We will understand why and how the dominant regime governing water management in the U.S. West came to be and why it continues to serve the economic accumulation and growth of non-Indian interests to the detriment of Indian claims today. And, we will come to a better understanding of how to rethink water management and conflict resolution in the West to help facilitate the decolonization of Indian waterscapes.

title: TWO ESSAYS ON INVESTORS' PERCEPTIONS ABOUT MANAGEMENT DISCLOSURES
abstract: In this dissertation, I describe two studies related to investors' perceptions about management disclosures.
In the first study, I use a variant of Dye and Sridhar (2004) to show analytically that investor uncertainty about managers' reporting incentives to manipulate information reduces the degree to which accounting reports should weight manipulable information. I also predict and show experimentally that greater weight on manipulable information in the face of incentive uncertainty harms investor welfare more than predicted by equilibrium analyses, by hindering managers' and investors' ability to predict one another's strategies. The resulting deviations from equilibrium cause the perceived and actual value-relevance of financial reports to vary over time in predictable (and testable) ways.
In the second study, I report an experiment that examines how investor affect might influence investors' perceptions of management disclosure credibility. Based on accounting and psychology literature, I predict that investors in a positive affective state will assess a higher level of management disclosure credibility due to positive interpretation and heuristic processing of information, and this tendency will be mitigated by their awareness of management reporting incentives. The results show that, inconsistent with prior evidence, positive affect does not lead to higher assessments of management disclosure credibility. Instead, positive affect is associated with a more systematic information-processing strategy. The results suggest that the psychology literature on affect need to be refined to be applied in a management disclosure setting.

title: Developing Handle System Web Services At Cornell University.
abstract: Recognizing the importance of consistently implementing persistent identifiers (PIDs), a group of librarians at Cornell University evaluated several PID strategies and chose to implement the Handle System. As a member of that group, the author immediately perceived cultural and technical challenges to adopting handles that included accommodating diverse computing platforms. The development of cross platform Web Services and corresponding client libraries are explored as a way to address these challenges and create new opportunities for future development and maintenance of digital collections.
